HE outlook after myocardial infarction has usually n assessed by comparing results of treatment in a few e patients with a simultaneous control series The atively small numbers in clinical trials (and in a disorder uch variable course 100 must be regarded as small), lead to chance results which are deceptive. In most he trials unequivocal diagnostic criteria have been anded, and these have usually been the characteristic ures that have been recognised for the past thirty s A positive diagnosis is almost irrefutable, and the errors are those of omission (Paton 1957) The ies of Björck et al. (1958) do not support the idea that nt improvements in finesse of diagnosis have added nts with improved survival prospects Before long- anticoagulant therapy was introduced there were y studies on prognosis, and to neglect them would be obbish ' (Björck 1960)

e begin by reviewing the more important of these w-up studies to reveal the factors on which prognosis depends We are not concerned with the vexed problem of immediate mortality in the acute phase (Morris et al 1952), but with the survival prospects of those who have recovered from a single recognised acute infarction Though we shall mention some studies which deal with first or subsequent infarctions, and some which include angina, these are mainly used to provide supporting data on certain aspects

Wider appreciation of the methods of calculating life-tables has compelled the discarding of many older studies where survival was estimated on patients who had died, and the recalculation of others such as the data of Sigler (1951) who tabulated the dead and living separately Other papers were discarded because of inadequate information on important influences such as age

Factors Influencing Prognosis

The more important studies on prognosis are summarised in tables Ia, Ib, and Ic, and are illustrated in figs 1 and 2 The studies on myocardial infarction total 5398 patients, while the series including angina adds another 8639 While five-year survival tends to cluster round 65–70%, it will be shown that survival is much better in younger patients who have made a good recovery and worsens with increasing age in those with extensive lesions, and with complicating conditions like hypertension and diabetes

Age and Sex

There is a striking difference between survival prospects in Waldron and Constable's (1950) series and those of Eckerström (1951) the average age in the former was 51 5 but the average age (66 7) of the latter series was obviously weighted by a substantial number in the eighth decade or over Inspection of table I shows a general trend to higher five-year mortality

TABLE Ia—PROGNOSIS AFTER SURVIVAL FROM THE FIRST MYOCARDIAL INFARCTION

Author	Patients		Start of follow-up	Percentage survival									
	Number	Mean age		1	2	3	4	5	6	7	8	9	10 (years)
s et al. (1952)	123	54	1 month	96		90		83					
and Marks (1953)	166	51·5	Disability benefit	93	84	81	76	70	67	63	58	54	53
(1953)	85		2 months	88		71		64					53
et al (1954)	285	57	2 months					67					44
(1956)	211	58	2 months	92	84	75	68	60	54	48	44	40	37
der and Levander (1959)	232	57	End of 1st admission					58					
et al. (1960)	427	53	2 months	92	86	79	73	69					
ms et al (1960)	235	62	1 month			69		55					29

TABLE Ib—PROGNOSIS AFTER SURVIVAL FROM FIRST OR SUBSEQUENT INFARCTION

Author	Patients		Start of follow-up	Percentage survival									
	Number	Mean age		1	2	3	4	5	6	7	8	9	10 (years)
tröm (1951)	109	66 7	1 month	67	51	41	36	30

Seim (1960)	372	26	15	23	13	23

* This figure applies to cases described as "coronary insufficiency"

† This figure applies to all cases of coronary heart-disease without evidence of acute infarction

These studies show that the chances of survival following acute infarction can be assessed by consideration of *age, sex, economic status, severity of the attack* and degree of recovery, and complicating diabetes or hypertension The slightest degree of unintentional bias in the selection of patients for treatment and control groups could profoundly influence the results

Anticoagulant Treatment

The use of dicoumarol and phenindione in the treatment of acute myocardial infarction has been followed by a significantly lower mortality during the acute phase Wright et al (1948) reported the results of the American Heart Association's trial which showed a 24% mortality in the control series compared with a 15% mortality in the treated In patients under 60 the crude death-rates were the same in both groups, but there was less nonfatal thromboembolism in the treated patients They accordingly advocated the use of anticoagulants in the acute phase, especially in patients aged 60 and over Feldman et al (1952) studied 189 patients, and did not find that mortality was reduced, or that thromboemboli were less frequent in a series of treated and control patients matched for age, sex, and cardiovascular status The work of Gilchrist and others in this country (Gilchrist and Tulloch 1956) has established a place for anticoagulant treatment in the acute phase, particularly to reduce thrombosis on the venous side, and subsequent emboli in the pulmonary and systemic circulations That these are the effects of anticoagulants is postulated by Bjerkelund (1957), but he cautiously states that "one is hardly justified in concluding that this form of treatment also prevents arterial thrombosis, including coronary thrombosis itself, which in many respects is thought to be of a different nature and related to other pathogenetic factors"

The claims of improvement in prognosis from acute-phase treatment have led to widespread interest in long-term treatment, but, in the absence of critical and controlled work, it is difficult to define the place of anticoagulants in preventing myocardial infarction Gilchrist (1960) admits that in our present experience, and in the absence of all the desirable evidence, the case for long-term anticoagulant therapy amongst those with permanent myocardial damage is "not proven", though the evidence in favour is very suggestive Writing before the Medical Research Council (M R C) (1959) report was published, Jordan and Punt (1958) suggested that "a study of the publications shows that—although the results are generally described as favourable—it is exceedingly difficult to use the figures given as a basis for a definite conclusion regarding this therapy"

Control Series

We have shown that the prognosis for survival after recovery from myocardial infarction is influenced by many factors affecting the results of any trial unless critically matched in control and treated groups Sometimes published results appear convincing until the control group is analysed Bjerkelund (1957) and the M R C (1959) studied patients who were matched accurately, but most other papers are less reliable

Lack of an Adequate Control Group

Keyes et al (1956) showed that mortality of their treated patients was 8 4% in four years compared with 41% in the same period in the untreated with first infarctions No facts are given about the age, sex, or history of either the control or treated group, the former being two-and-a-half times as large as the group of 71 trated patients, suggesting some selection

Tulloch and Wright (1954) studied a very small group (32 patients after the late phase of myocardial infarction) with a fifteen-month mortality of 6 2%, but they gave no facts about their patients, and so it is impossible to assess the results, and, in any case, this mortality does not differ significantly from the upper range of large untreated series (fig 8)

Ensor and Peters (1959) used a "pseudo-control" group—i e, a group of patients who had had anticoagulants for some time but who had discontinued treatment The only fact given about the patients is the severity of the myocardial infarction in the treated group, but these authors are cautious in their claims as they only report a 79% five-year survival in treated patients against 70 7% in the "pseudo-controls"

Nichol et al (1958) studied the effect of anticoagulant treatment in patients with impending infarction, or in

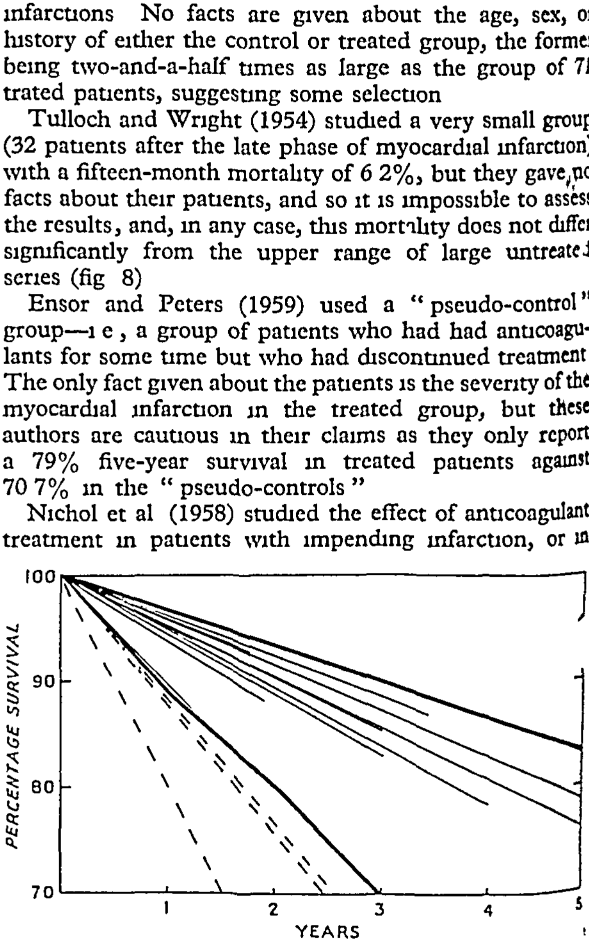

Fig 8—Treated series compared with untreated

The general prognosis derived from fig 1 lies between the thick lines The survival of treated patients (continuous lines) is shown using survival table data or percentage survival at the end of the average length of treatment The treated series from above down are (1) Tandowsky (1959), (2) Muri (1956), (3) Ensor and Peters (1959), (4) Suzman (1959), (5) Ødegaard (1958), (6) Tulloch and Wright (1954), (7) Bjerkelund* (1957), (8) Waaler† (1957), (9) Nichol et al (1958), and (10) Nichol and Bork (1950) The controls (dot-dash lines) from above down are those of Nichol et al (1958), Bjerkelund (1957), and Suzman (1959) While the treated series tends slightly into the upper range of survival, the controls fare worse than usual

* Based on total deaths † Includes patients with angina

with one or two previous infarctions They used controls, however, patients from their records who been previously followed up without any treatment ney also named a group of patients who abandoned -term treatment It is significant to note that 14% the deaths in this group occurred within one month stopping anticoagulants But none of the groups matched and the average period of follow-up in each Their treated patients showed an 88% vival after an average period of 1 87 years, well within ns of past experience (fig 8)

Suzman et al (1955) present formidable figures to that patients on long-term treatment do better than treated during the acute phase only Although this a careful study, the chief drawback to their results is " the final decision for long-term treatment was left the patient " Economic factors obviously entered into selection, and the results of treatment were a five-year val of 76 1% against 45 6% in the untreated cases uzman (1959) has kindly allowed us to see his unpub- figures which show that recurrent infarction ccurred only slightly less often (34 7% against 43 2%), its mortality was less (40 5% against 74 8%) in long- treatment patients than in the short-term group results, however, must be seen against the background of the selection of patients and the age-distribution of the groups, 31% of the patients in the short-term group were over 70, compared with only 20% in the -term group

Tandowsky (1959) does not mention his patients' status, except to describe the 70 controls as " a like group " in whom the mortality (53%) was four times that of the treated (13%), the average duration of treatment was three years and five months

Use of Retrospective Studies to Provide Control Groups

Some papers which have given encouraging figures for urvival in patients treated with long-term anticoagulants not had a concurrent control series Some writers have compared a series of patients treated in one country ith a series reported in a different country some years efore. Thus, Muri (1956) who had a 7 5% mortality an average exposure to risk of twenty-one months ompared his results with those of Parker et al (1946) which were later included in the total series of Block et al 1952), both reporting an exceptionally high (19 and 16% espectively) first-year mortality Waaler (1957) who chieved a 17% three-year mortality, also used as controls he data of Block which are seen to be much worse than hose of Sigler or Seim (table IC)

Tanzi and van Ness (1957) compared their mortality f 6 1%, in a sixteen-month average, with those " so far eported " Toohey (1958), who had an 11 6% mortality t eighteen months, used as controls patients who had een followed up after myocardial infarction in the same nd another hospital during the seven years before long- erm anticoagulants this series had a 33% two-year mortality Toohey did not mention either age or sex mong his patients, and so it is not easy to accept the laim that his results are " statistically significant " His ontrols, who had a much higher mortality than usual, ay have been an aged group, and his treated patients ere not matched with the controls in any way

dmission to Treated Group and Follow-up Care

Tanzi and van Ness (1957) and Keyes et al (1956) mited their treatment to those who could cooperate The former achieved 6 1% mortality in sixteen months while the latter had a 9 9% mortality between one and thirty-eight months of observation, results which lie within upper range of life expectation as shown in fig 1 The striking five-year survival, 83%, which Morris et al (1952) reported in medical practitioners, demonstrates the part played by intelligence, social status, and careful follow-up in survival after myocardial infarction Constant supervision is certain to ensure earlier treatment of symptoms which may arise, and this is the only way in which the control group of patients in Bjerkelund's (1957) admirable study differed from the treated group The latter were seen every one to three weeks against the three to four monthly intervals between the visits of control patients

Results of Treatment

Although many reports have an inadequate control series, they give valuable facts about survival in the treated patients

Survival of Patients

Many of the earlier papers included a few patients with myocardial infarction, and a larger series treated with long-term anticoagulants for thromboembolic disease, and so are not satisfactory for survival data Tulloch and Wright's (1954) and Muri's (1956) figures have already been discussed Nichol and Borg (1950) treated 78 patients for an average of fifteen months and reported a 15 3% mortality, which is less good than the average (fig 8) Ødegaard (1958) treated 117 patients, of mean age 58 9 for a total of 343 patient-years, and found a mortality-rate of 4 87% per year—a little better than average but not outside the range of untreated patients There was a 10% mortality in 735 patients with one infarction, studied for an average of twenty months by Nichol et al (1958) they also reported an overall mortality rate of 12% in 1091 patients with impending one or two infarctions, studied for an average of 22 4 months Both these figures are within " untreated " expectation Manchester (1957) expresses his results as the fatality, and number of recurrent infarctions per 100 patient-years, these figures were 0 56 and 2 73 respectively A survival table cannot be made from his data He had twice as many patients with heart-failure requiring digitalis (33%) in his control group as in his treated group (15 6%) The five-year survival of 76% in Suzman's (1959) treated patients may well reflect the better social status of his patients

The chief interest in the reports of Bjerkelund (1957) and the M R C (1959) is the difference which is shown between the control and treated patients during the early months of long-term treatment Bjerkelund (1957) stated that the " force of mortality " seemed to be largest initially in the control group, and that the treated patients—but only those under 60—did not show this initial excess mortality It is noteworthy that in both Bjerkelund's and the M R C series, most of the excess deaths in the controls took place in the first three months after infarction Bjerkelund reported no statistical difference between the " force of mortality " in the treated and control group at any age, a year and more after infarction (see figs 5 and 6 of his monograph) The M R C trial showed a similar trend, and although 19 of the 28 deaths in the low-dosage group occurred in the first six months compared with only 9 of the 17 deaths in the high-dosage group " the difference in the death rate was appreciable only during the first three months of the follow-up period " These results are best demonstrated by the death-rates per 100 man-months of exposure during the first year

Period	*Low dosage*	*High dosage*
Less than 3 months	2 7	0 8
3-6 months	1 7	1 1
6-9 months	0 8	0 5
9-12 months	0 0	0 8

While both these reliable reports show similar results, the efficacy of anticoagulant drugs was only transient Suzman (1959) and Manchester (1957), however, report sustained improvement of prognosis, and so these four important protagonists are far from agreement on the reasons for their advocacy of long-term treatment

No reported series shows that anticoagulant treatment in any way affects the pattern of an increasing mortality with age, or benefits older patients This is thoroughly borne out by Bjerkelund's (1957) results with his older (over 60) patients, whom treatment did not benefit Similarly, the difference between the low-dosago and high-dosage groups of men aged 55 and over was less marked than that in men under 55, which itself did not reach the 5% level of significance (M R C 1959)

These results, and those which have been given above, show that it is probably only in the acute and healing phases of myocardial infarction that anticoagulant treatment may be effective in increasing survival, but even this is not yet statistically proven Long-term anticoagulant prophylaxis beyond about two months after infarction cannot yet be justified by adequate evidence

In small numbers of patients—and we must count the M R C and Bjerkelund series as small—there are obviously possibilities of great variability indicated by "highly significant" results diminishing with the passage of time to statistical "insignificance" in both series That chance could readily operate to account for the results is borne out by the recent work of MacMillan et al (1960) In a statistically randomised series of 27 treated and 23 untreated patients, they had 8 deaths in the treated as against none in the untreated "controls"

Recurrence of Infarction During Treatment

The difficulties of establishing this diagnosis have already been mentioned, and the papers which report the results of treatment are not precise in defining the criteria for a recurrence Bjerkelund (1957) alone classifies his patients into those with definite, very probable, and probable recurrences, and he points out that the diagnosis could not be established with equal certainty in all cases However, the diagnosis of his recorded instances was definite in 63 5% of treated, and in 76% of untreated patients He is careful to state that cases of sudden death were only included as recurrent infarcts if definite signs of a fresh infarct were found post mortem Thus, his criteria differ from those of the M R C report (1959) in which all cases of sudden death were attributed to recurrent infarction Manchester (1957) does not mention the criteria for recognising a recurrence These divergences explain the varying results of table III, where the incidence and mortality of recurrences in treated patients are shown. The apparent tendency towards a lower rate of reinfarction in the treated patients is open to critical doubt on account of the above difficulties of controls and diagnosis.

Certain facts must be emphasised which arise from this study of reinfarction Bjerkelund (1957) makes a thorough study of the "force of recurrence" in his control group and shows a definite "excess of recurrences" in those under 60 during the first six months—but shows that this is not significant in the patients more than 60 years old Moreover, after twelve months he can find no statistical difference between the "force of recurrence in the treated and control groups, and he finds that anticoagulant therapy has not given much protection to those with a high "force of recurrence"—i e , those with a previous recurrent infarction He claims that during the observation period two-fifths of the recurrent infarctions and at least half of the deaths due to recurrences were prevented by dicoumarol treatment His most significant differences, however, were either in the first month of observation (i e , near the acute phase) or in patients over 70

The M R C (1959) data on recurrent infarction differ from those of Bjerkelund in suggesting that a disparity in infarct-rate between high-dose and low-dose patients continues into the second year of follow-up Although there were fewer cases of recurrent infarction among the treated, 17 out of 24 died from their recurrence, against 29 out of 60 in the low-dose group

A reduced incidence of recurrent infarction in treated patients was also reported by Manchester (1957) and his results appear to be formidable evidence, but he did not give details of the patients studied, nor any criteria for the diagnosis of a recurrence A large number (157) of his patients abandoned treatment, and these may have weighted survival in those continuing treatment towards a better prognosis, with fewer recurrences, as the M R C report suggests

Suzman (table III) also found a slightly lower rate of reinfarction in his long-term treated patients, especially in those whose previous infarction had been severe However, the mortality of recurrent infarction was higher in the control group (49 4% against 27 6%) It is noteworthy that the mortality in Suzman's "treated" recurrences was about half that in the M R C series where it was remarkably high (75%) Bjerkelund (1957) found that patients with a mild previous infarction had fewer recurrences, whereas Suzman (table III) found the reverse Recommendation of long-term anticoagulants is thus based on widely divergent findings

TABLE III—RECURRENT INFARCTION IN TRIALS OF TREATMENT

Author	Number of patients		Period of study (years)	Recurrence of infarction			
				Control		Treated	
	Control	Treated		Incidence (%)	Mortality (%)	Incidence (%)	Mortality (%)
Keyes et al (1956)	231	121	2	38 0		2 0	
Bjerkelund (1957)	118	119	3	40 (*a*)	41 6	22 (*a*)	34 6
Manchester (1957)	200	204	10	31	53 0	14 2	20 6
Nichol et al (1958)		1091	1 87			10 75 (*b*)	66
Medical Research Council (1959)	188	195	3	27 5	46 5	12 3	75
Suzman (1959)	216 (*c*) mild	55	10	32 8	19 4	34 5	27 6
	298 (*c*) severe	115	10	50 7	61 4	31 8	38 3

(*a*) Includes cases classified as definite, very probable, and probable myocardial infarction
(*b*) Includes cases described as ventricular fibrillation or cardiac arrest (i e , sudden death)
(*c*) Refers to severity of first attack of infarction

to Work

It has already been shown that many patients are able return to work, and to stay at work after recovery myocardial infarction without long-term treatment. is disappointing, therefore, that Bjerkelund (1957) d that only slightly more treated than control patients d to work. The small difference between the two ups probably depended upon more elderly patients mong the controls Bjerkelund states that the "difference hardly gives reason to believe that the treatment has uced the patient's ability to work" The M R C 1959) found that there were slightly more men at work n the treated group (83% against 71%), but the proportion without dyspnœa was the same (66% and 67%) This s the more remarkable as the 31 of the "untreated" vivors had had an additional recurrent infarction Muir (1956) reported that 79% of treated patients were work, a figure in agreement with the M.R C treated and untreated groups, and thus hardly to be claimed as a erapeutic success

A patient's return to work will in part be determined by his symptoms A common symptom which can limit his return to work is cardiac pain, which has been reported be less frequent in patients treated with anticoagulants We wish, however, to repeat Bjerkelund's (1957) statement that "cases of angina pectoris often have spontaneous fluctuations, and this makes assessment of prophylactic therapy very difficult"

Manchester (1957) found that 38 of 74 treated patients had less cardiac pain, compared with only 20 of 72 control patients imilar figures were given by Tandowsky (1959) for the abatement of coronary insufficiency, and Waaler (1957) found that 8% of his series of treated patients with angina pectoris were wholly relieved, and 12% were partially relieved of pain. The M.R.C (1959) reported that the absence of anginal pain uggested a slight superiority among the treated (64% against ?%) over three years of study Bjerkelund (1957) meticulously ubdivided his patients according to their grade of cardiac , but was not convinced that dicoumarol had any "definite" prophylactic effect against this symptom.

Thromboembolism

The prevention of venous thromboembolism after the nitial acute phase does not receive much prominence in ny report, and it is evident that it is not very important linically after the acute phase, though when it is recognised, the mortality is high

Manchester (1957) reported 35 cases (17 5%) of whom 16 45 7%) died in his untreated group, against only 5 8% with 14 2% mortality in his treated patients Bjerkelund (1957) ound extracardiac thromboemboli in only 2 of his control group, and in none of his treated group Suzman (1959) ound thromboembolism three times more frequently in his ntreated patients Only 1 case is mentioned with a fatal cerebral embolus in the M.R.C low-dosage group It seems ikely that patients on anticoagulants are protected from venous hromboembolism (Sevitt and Gallagher 1959)

There is adequate postmortem evidence, however, that oronary arterial thrombosis can, and frequently does, levelop in patients under expert anticoagulant control Fresh coronary-artery thrombosis was found at necropsy n 58% of Bjerkelund's untreated patients, and, post nortem, in 26% of his treated patients Capeci and Levy 1959) were not impressed by any diminution of thrombus ormation in treated patients who came to necropsy

ndications for Treatment

Two different opinions are held about choice of patients or, and duration of, treatment Nichol and Fasset 1947) decided to use anticoagulants for patients with recurrent infarction Wright et al (1954) and Suzman et al (1955) also reported that this type of patient might benefit from treatment The M.R C (1959) found that a lowering of the infarction-rate appeared most clearly in those in whom the risk of recurrent infarction was high, in younger males, and in those with more than one infarct On the other hand, Bjerkelund's results indicated that there was no benefit from treatment in patients who had had more than one infarct he would recommend treating all, or a large number of, patients for six months or a year, but not thereafter The M R C report, however, recommends that "continuous" treatment should be given as this can make a useful if limited, contribution in the aftercare of patients who have recovered from the acute phase of myocardial infarction, in spite of their own evidence that the regime is of little value after six months

Discussion

At the beginning of this paper, we showed that patients who survive the acute phase of a myocardial infarction have a five-year survival-rate of about 66% This figure has varied according to the type of patient who has been followed up, ranging from above 80% in the doctors studied by Morris et al (1952) to 30% in Eckerstrom's (1951) elderly patients We have mentioned the remarkably good five-year survival figures for patients who make a complete clinical recovery, or who are young at the time of their infarction All this evidence shows that myocardial infarction may often be followed by long survival The various factors which affect prognosis have been documented in order to give a background of experience against which the results of long-term prophylaxis may be reviewed

In studying the published reports on anticoagulant prophylaxis, we have become critical of the controls, who have often been at, or below, the lower extreme of prognosis found in untreated patients, while the treated fare no better than those in the upper range of survival prospect (fig 8) The careful studies of Bjerkelund (1957) and of the M.R C (1959) have been a constant source of valuable data, but there is surprisingly little work of similar calibre in other studies

Despite many claims, the evidence that long-term anticoagulants prevent recurrence, or reduce mortality, after the acute phase of infarction is still inadequate Most of the benefits reported by Bjerkelund and by the M.R C working party occurred in the first few months —i e, while patients were still recovering from the acute event If the action of the drugs is to prevent arterial thrombosis, there is no reason why this prophylactic action should cease after a few months, and it may well be that the early benefits reported in the Bjerkelund and M.R C series are in fact related in some way to the early healing phase of the actual infarction Another possibility is of harm to the controls from sudden termination of acute-phase treatment.

It seems possible that most of the benefits which have been reported in the acute phase of infarction are related to the efficacy of the drug in limiting venous thrombosis and preventing pulmonary embolism, most reports are consistent in this respect. The recent studies by Sevitt and Gallagher (1959) on prophylaxis of venous thrombosis with phenindione in patients with fractured femora are most encouraging The apparent failure of the same measures to prevent coronary occlusion is all the more disappointing Antiprothrombin drugs have also failed in cerebrovascular occlusive disease (Marshall and Shaw

1960), and in occlusive arterial disease of the legs (Singer and Rob 1960)

Venous and arterial thromboses probably differ considerably in their pathogenesis Venous thrombosis is undoubtedly promoted by stagnation in veins of the calf, often subjected to prolonged mechanical pressure in bed in debilitated patients Arterial thrombosis, on the other hand, is based on underlying disease of the arterial wall—atheromatous plaques and ulcers, which can liberate local tissue thromboplastins into the blood-stream, which in turn may be retarded by upstream narrowing of the vessel Ischæmia and myocardial infarction have been reported in patients with hæmophilia (Boivin 1954, Borchgrevink 1959, Stewart and Acheson 1957) The development of arterial occlusions in these patients reinforces the importance of local release of thromboplastin from the damaged intima as a crucial event in the changes leading to thrombosis, even of hæmophilic blood (Astrup et al 1959) Mural thrombi over infarcts form with almost equal frequency in patients on anticoagulants as compared with controls (Gilchrist and Tulloch 1956) Such observations raise serious doubts on the usefulness of anticoagulants in preventing local thrombosis on damaged arterial intima

Any problematic benefit from anticoagulants in the prevention of thrombosis should be weighed against the considerable risk of hæmorrhage mentioned in most reports Lethal cerebral hæmorrhage occurred in 4 out of 118 patients in Bjerkelund's (1957) series, 2, and possibly 3, fatalities were also recorded from Newcastle (Fuller 1959) Quite apart from the risk of cerebral and other fatal hæmorrhages, morbidity can result from serious bleeding from anticoagulant treatment Anticoagulants may not avert arterial occlusion, and there is a real, and probably increased, risk of thrombosis in the period immediately after the drugs are stopped Various reports have suggested that sudden cessation of antiprothrombin drugs may be followed by arterial occlusion within a short time (Nichol et al 1958), 20 such instances are documented by Dinon and Vander Veer (1960) It is not impossible that this complication may have been responsible for the early high mortality, so near the end of acute-phase treatment, in both the M R C and the Bjerkelund control patients Hence, when anticoagulants have been used in the acute phase of myocardial infarction, their administration should be tapered off over a period of three to four weeks

Finally, it is well to remember that factors other than thrombosis also play a part in the production of myocardial infarction Among them are thickening of the atheromatous plaques themselves, subintimal hæmorrhage (Paterson 1936, Paterson et al 1957), and sudden falls of blood-pressure reducing perfusion of critically narrowed coronary vessels Furthermore, recurrent thrombosis may be responsible for a little more than half the ultimate death-rate in patients who have recovered from a cardiac infarction

Summary

The survival of patients after recovery from myocardial infarction, and the factors which influence prognosis, have been studied from reported series

There is broad agreement in the published data, totalling over 5000 patients (table 1a and 1b), that the prospect of five-year survival in cases under 60 ranges round 66%, being worse with increasing age and complications, and better with improving social circumstances and completeness of recovery

Long-term anticoagulant prophylaxis, as carried today, shows no evidence of improving life when compared with the prognosis in this large of " untreated " patients

Possible reasons for this inefficacy of long-term an coagulant prophylaxis are briefly discussed against background of contrasting mechanisms of arterial venous thrombosis The possibility should also be considered that some of the early high mortality in " controls may be the result of sudden cessation of " treatment "

We are particularly grateful to Dr M M Suzman and Dr MacMillan for putting their unpublished data at our disposal

POTASSIUM IN THE TREATMENT OF CHOLERA

RAYMOND H WATTEN
B.A , M D Stanford
ROBERT A PHILLIPS
M.B E , M D Washington, St Louis, B S Iowa
MEDICAL OFFICERS, UNITED STATES NAVAL MEDICAL RESEARCH UNIT NO 2, TAIPEI, TAIWAN (FORMOSA)

Sir Leonard Rogers, in 1909, advocated the use of a ypertonic solution containing sodium chloride, calcium chloride, and 0 4 g (5 4 mEq) per litre of potassium chloride, for the treatment of cholera, but in 1916 he decided to omit potassium from the mixture because 'some physiologists consider it unnecessary and possibly harmful" In 1946, Govan and Darrow demonstrated a fivefold reduction in mortality from infantile diarrhœa when potassium was added to replacement solutions used parenterally Electrolyte studies by the United States Navy in the 1947 Egyptian cholera epidemic showed an excessive loss of potassium in the stools, hence it was recommended that potassium 6 7 mEq be included in each litre of intravenous solution used in the treatment of cholera (Johnson et al 1948) Chakravarti and Chaudhuri, in 1954, recommended giving potassium salts, when the acute diarrhœa of cholera had subsided, to hasten convalescence, providing that renal function was satisfactory Despite the above, a recent review of cholera therapy (Pollitzer 1957) does not mention the use of potassium in the treatment of the acute disease

The Study

During the 1958 cholera epidemic in Bangkok Thailand, eventeen patients with proven cholera were studied intensively during their acute illness For the first 24 hours nothing was allowed by mouth in order to relate the fæcal changes to changes in plasma-electrolyte composition Thus, during the first 24 hours, fluids were given exclusively by the intravenous route. Meanwhile balance studies were made, and afterwards a diet of boiled eggs, rice gruel, milk, and water was given ad libitum The fæces and urine were collected and measured daily until the patient was discharged. A detailed report of his investigation, including methods and procedures, has been published (Watten et al 1959) While it is impossible from hese studies to calculate balance data for more than 24 hours fter admission, approximate potassium losses during the 2–4 days of diarrhœa may be calculated

TABLE I—MEAN HOURLY FÆCAL VOLUME AND ELECTROLYTE CONCENTRATION OF CHOLERA STOOLS COLLECTED OVER 24-HOURS

—	Volume (ml. per hr)		Electrolytes (mEq per l)			
	Mean	Range	Na	Cl	K	HCO_3
11 patients with fæcal volume over 125 ml. per hr	340	130–730	137	107	16 1	45 2
patients with fæcal volume under 125 ml. per hr	100	23–120	114	89	26 4	43 5

Patients with severe cholera had 24-hour fæcal volumes of –17 litres In these patients the total volume of diarrhœal uid during the 2–4 days of the disease was 10–35 litres During the 24-hour balance period, the mean potassium ontent of the fæces was 16 mEq per litre (table I), and otassium losses in fæces and urine averaged 158 mEq , with range of 50–245 mEq The total fæcal and urinary loss of otassium for the entire period of diarrhœa varied from 400 to 700 mEq , or, for a 50 kg man, the loss was 15–30% of the total exchangeable body-potassium, assuming this value to be 9 mEq per kg body-weight for a normal man (Edelman and eibman 1959)

Fæcal potassium concentrations vary inversely with fæcal volume (Watten et al 1959) Table I shows that patients with fæcal volumes in excess of 3 litres per day (125 ml per hour), had fæcal sodium and chloride concentrations which were nearly isotonic with those of the plasma, while the potassium and bicarbonate concentrations were higher than the plasma levels

With amelioration of diarrhœa and decrease in fæcal volume, the potassium concentration increased while the sodium concentration decreased, this is related to selective reabsorption of sodium in exchange for potassium in the lower ileum and large bowel, and it has been demonstrated experimentally by D'Agostino et al (1953) Paralytic ileus, with abdominal swelling and cessation of diarrhœa, was often seen in patients whom we studied during the 1958 Bangkok cholera epidemic

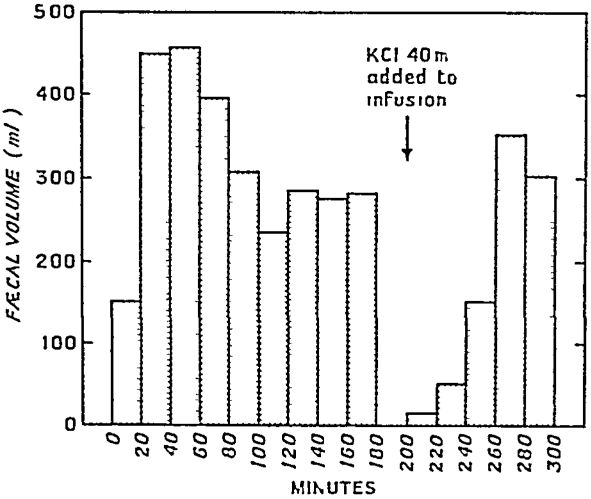

Fig 1—Fæcal volume measured at 20-min intervals during constant infusion (15 ml per min) of normal saline (4-140 min) and 2% sodium bicarbonate (140-240 min)

This complication, as Wilkinson (1943) pointed out, is probably responsible for the rare examples of so-called cholera sicca, in which death results from massive transfer of fluid into the bowel lumen without diarrhœa

Fig 1 shows 20-minute fæcal volumes in a patient during infusions of normal saline and 2% bicarbonate solution The drop in fæcal volume at 180 minutes was probably the result of potassium deficiency, because balances at that time revealed a loss of 165 mEq of potassium Fæcal volume increased after infusion of 40 mEq of potassium chloride, and then it remained constant with additional infusions of potassium The sequestration of a large volume of diarrhœal fluid in the bowel, caused by paralytic ileus, can be misleading and dangerous if fluid therapy is based on replacement of observed fæcal volume alone Utilisation of more accurate measurements of dehydration, such as plasma-specific-gravity determinations (Phillips et al 1950) will prevent such errors

During our cholera studies, alkalosis developed after treatment in four patients who had been given only 20–80 mEq of potassium (replacing about 10% of the deficit) during treatment (table II) The plasma-CO_2 content remained above 30 mEq per litre for as long as 7 days after the diarrhœa

TABLE II—ADMISSION AND CONVALESCENT PLASMA-CO CONTENT AND POTASSIUM LEVELS IN FOUR PATIENTS WITH SEVERE CHOLERA

Patient no	24-hr fæcal volume (ml per hr)	Plasma CO content (mEq per L plasma-water)		Plasma-potassium (mEq per l plasma-water)		Interval (days)
		Admission	Con-valescent	Admission	Con-valescent	
2	476	22 2	29 3	4 5	3 8	7
10	235	14 0	37 0	4 8	3 3	6
12	302	11 1	30 4	4 3	3 1	3
15	725	20 5	33 3	4 9	3 4	7

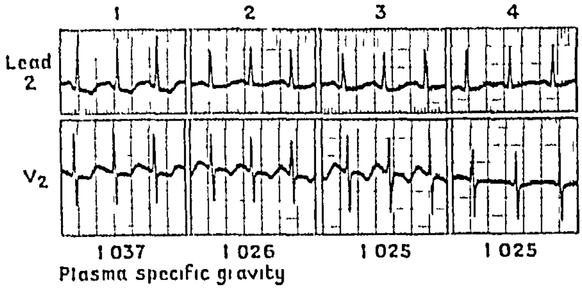

Fig 2—Patient no 6, 30 year-old Thai woman, 24-hour fæcal volume 7700 ml

The tracings were made (1) on admission at 12 30 A M (plasma-CO_2 content 15 mEq per litre), (2) at 2 P M after rehydration with 3 litres of normal saline, (3) at 4 30 P M after infusion of 500 ml of 2% sodium bicarbonate solution (which raised the plasma-CO_2 content to 22 mEq per litre, and (4) at 5 30 P M after infusion of 10 mEq of potassium chloride in 1 litre of normal saline

ceased, despite a normal diet The data were not complete enough to indicate the pathogenesis of alkalosis associated with potassium deficiency in cholera, but they do indicate that a moderate alkalosis developed in several patients with serious potassium depletion, who had been treated with adequate quantities of saline and bicarbonate

Serial electrocardiograms were taken during treatment of thirteen patients, but only five showed definite evidence of potassium deficiency either before or after the dehydration had been corrected with saline Fig 2 shows the changes in a patient with severe cholera During the 5 hours before admission this patient passed seven watery stools, and was moderately dehydrated The first tracing, taken 6 hours after the onset of the patient's diarrhœa, showed T-wave alterations in all leads T-wave changes were less pronounced after saline and bicarbonate infusions, but they did not return to normal until potassium had been given These changes were not caused by dehydration because plasma-specific-gravity values were within the normal range during the infusion therapy

Discussion

Rational treatment of cholera requires knowledge of the altered physiology and chemistry of this disease Such information has not been available until recently (Watten et al 1959), and consequently therapeutic regimens have changed little since Rogers' recommendations of 50 years ago There is universal agreement on the necessity for prompt replacement of water and salt, and the use of bicarbonate for the treatment of acidosis is accepted, but the risk of pulmonary œdema from overhydration (Chaudhuri 1950, Chakravarti and Chaudhuri 1954) is emphasised far more often than the danger of insufficient fluid replacement Myocardial depression caused by potassium depletion rather than by rapid replacement of fluid may well be the important factor in the genesis of this complication Death from "heart-failure" during convalescence (Baligh 1948) may also be due to deficit of potassium Moreover, adjuvants to therapy (colloid plasma-volume expanders, cardiac stimulants, vasopressor agents, bacteriophage, antibiotics, &c) continue to be given emphasis out of proportion to their value, and they detract from what should be the main line of cholera therapy—i e , replacement of the lost water and electrolytes

A lesser-known result of potassium depletion is renal tubular damage, vacuolisation of distal tubular cells, and damage to the collecting tubules, have been reported (Relman and Schwartz 1958, Holliday 1959) In a recent study of patients dying in uræmia after cholera, Benyajati et al (1960) found microscopic changes in renal structure similar to those produced by potassium depletion Ischæmic renal damage and uræmia due to delayed or inadequate fluid replacement is a frequent complication of cholera Damage to kidney structure and impairment of function produced by potassium loss may contribute to renal failure in these cases

Neuromuscular disturbances are a well-known complication of potassium deficiency But there is only one report of transient potassium-depletion paralysis following cholera in eleven convalescent patients, this promptly subsided after potassium-chloride infusions had been given (Huang and Mao 1947) Instances are known of "secondary collapse" involving weakness, muscular twitching, and tetany during convalescence from cholera (Dr C Benyajati, personal communication)

Although plasma-potassium levels will eventually reflect potassium deficits, determinations made during the acute phase of cholera are of no value in establishing the need for potassium replacement Data from our studies (Watten et al 1957) indicate that plasma-potassium levels in acutely dehydrated patients were within the range of normal when corrected for plasma-protein concentration (expressed as mEq per litre plasma-water) Furthermore, plasma-potassium values after rehydration were also within the range of normal These findings indicate, as Scribner et al (1958) concluded, that plasma-potassium concentration is independent of the volume of the extracellular space

Saline solutions have been the foundation of cholera treatment Table I shows that, for each litre of fæces lost from a patient with severe cholera, a litre of approximately isotonic saline will replace the salt lost Theoretically, each litre of replacement solution should also contain about 16 mEq of potassium and 45 mEq of bicarbonate to replace these electrolytes

The amount of potassium required to replace the deficits in acute cholera should be sufficient to prevent complications without producing toxicity Ideally, measured potassium losses in urine and fæces would be exactly replaced, but facilities for this are rarely available in areas where cholera remains a problem, and even if they were the demands on time, personnel, and the laboratory during an epidemic would preclude their use except in the exceptional patient

It therefore seems advantageous to add a small amount of potassium to each bottle of replacement solution But the rapid infusion of 3–4 litres of a potassium-containing solution during the initial treatment of shock and collapse might increase the plasma-potassium levels too much, with the danger of heart-block and other conduction defects Until further information is available it is advisable to use parenteral potassium only after the initial dehydration has been treated, and when maintenance solutions are given more slowly

For the treatment of potassium depletion in infantile diarrhœa, Govan and Darrow (1946) recommended a solution containing 35 mEq of potassium per litre which he never gave at the rate of more than 120 ml per hou In adults, Nadler et al (1950) reported no untowar effects in treating the potassium depletion of diabet acidosis and prolonged vomiting with an isotonic solutio of potassium chloride (155 mEq per litre) given intravenously at a rate of 290 ml per hour (45 mEq potassiu per hour) But these infusion rates are far less than we have found necessary to maintain hydration in cholera patients, and an infusion-rate of 100 ml per minute is

, for the rapid treatment of collapse during the period of rehydration

Without electrocardiographic or laboratory control, which is impossible during the treatment of large numbers of acutely ill cholera patients, a solution is needed that is safe under a variety of conditions The addition of 10 mEq (7 5 g) of potassium chloride to 1 litre of saline should satisfy this need, and during an epidemic this solution could be used with safety in remote areas, even without medical supervision It will replace at least half the initial potassium deficit in the average severe case, and it should prevent the major complications of potassium deficiency As long as diarrhœa continues 10 mEq potassium may be added to each litre of maintenance solution with impunity, even when the renal function is unknown because potassium will continue to be lost in concentrations of 10–50 mEq per litre of fæces (Watten et al 1959) With cessation of diarrhœa, if renal function is not satisfactory, potassium should be discontinued In uncomplicated cases, 10 ml of a palatable mixture containing 100 g each of potassium citrate, potassium acetate, and potassium bicarbonate per litre of water may be diluted and given by mouth three times a day as soon as nausea and vomiting cease

From the electrolyte data reported in this paper, and from knowledge of experimental and clinical potassium depletion, one can conclude that the recommended addition of potassium should provide a more physiological approach to cholera therapy, diminish complications, and further reduce the mortality-rate

The opinions and assertions contained herein are those of the authors and they are not to be construed as official or as reflecting the views of the Navy Department or the Naval Service at large.

“ One of the explanations why people in general are rather well satisfied by living and working in these regulated national communities of the Western World is undoubtedly that they do not notice the controls so much, or do not react so violently, as they are becoming accustomed to them The present level of taxation in all Western countries, for instance, would have been unthinkable fifty or even twenty years ago There is a deep truth in Albert Einstein's observation that if there were beings who were flat and without thickness and who lived on the surface of a sphere, they would have no idea of a third dimension Like domesticated animals, people growing up in the Western type of regulated national communities have no real conception any longer of a wilder life. To the reflecting social scientist the adaptability of the human animal to new conditions will never cease to be one of this world's wonders ”
—GUNNAR MYRDAL. *Beyond the Welfare State* London 1960

FALLACIES IN INTERPRETATION OF QUECKENSTEDT'S TEST

A R TAYLOR
M.A., M B Aberd, F R.C S.E
NEUROLOGICAL SURGEON, ROYAL VICTORIA HOSPITAL, BELFAST

IN 1916 Queckenstedt introduced his test for the detection of spinal subarachnoid obstruction He noted that compression of the jugular veins caused a “congestion of the brain”, and consequent increase in the cerebrospinal-fluid (C S F) pressure In the presence of an expanding spinal lesion sufficient to block the subarachnoid space, this increase is not transmitted to the spinal canal, and is therefore not reflected in the fluid level of a lumbar manometer Queckenstedt wrote of congestion of the brain Had this conception been retained, and not replaced, as it was, by that of increased intraventricular pressure, later confusion might have been avoided As the original test was modified, and combined cisternal and spinal puncture methods were introduced to define the site of obstruction more precisely, inaccuracies in the interpretation of results appeared

The first refinement was added by Ayer (1921) who, having perfected his technique of cisternal puncture, used it in combination with lumbar puncture to show a rise in cisternal pressure without a coincident lumbar increase as additional evidence of spinal obstruction.

About 1924, at least three workers—Fremont-Smith, Cushing, and Eskuchen—independently described a method of combining ventricular with lumbar puncture to confirm the diagnosis of posterior-fossa obstruction, but here conditions are dissimilar to those in the spinal theca, and the test thereby becomes less reliable

Further improvements in detail were added. Poppen and Hurxthal (1934) pointed out that before evidence of block is manometrically apparent, the subarachnoid obstruction must develop to a degree in which the area left for fluid circulation is less than the area of cross-section of the spinal-puncture needle. Stookey and Klenke (1928) placed the test on a firmer mathematical and mechanical basis by explaining the delayed rise and the rise maintained after removal of jugular compression. Grant and Cone (1934) applied graduated pressures to the neck by a manometer cuff in steps of 5 and 10 mm Hg and recorded them, with successive C.S F-pressure readings, on a chart. This obviated the individual variants of degree and site of finger compression, and gave comparable records compiled by different observers

Antoni (1931), at the Copenhagen clinic, modified the combined cisternal and spinal test. He postulated that, as the superior caval venous pressure decreased with the inspiratory expansion of the thoracic cage, and the inferior caval venous pressure increased with the descent of the diaphragm the cisternal level should fall and the lumbar pressure rise with each inspiration, if a block existed between the needles Wagner (1947), reporting over 800 double punctures from the same clinic, concluded that the test for “respiratory block” was not reliable because the communicating vertebral venous system equalised the pressure between the superior and inferior caval systems

In the “reversed Queckenstedt test” saline is injected into the sacral epidural space raising the pressure at that level The absence of a corresponding rise at a higher lumbar site signifies subarachnoid obstruction between the two needles

As a result of these combined methods, many observers, instead of thinking in terms of venous distension causing increased pressure, thought instead of columns of C.S.F moving from one part of the cerebrospinal axis to another For example, Elsberg (1941) said “The compression of the jugular veins causes a venous congestion within the cranial cavity, and as a result, the expulsion of C S.F from

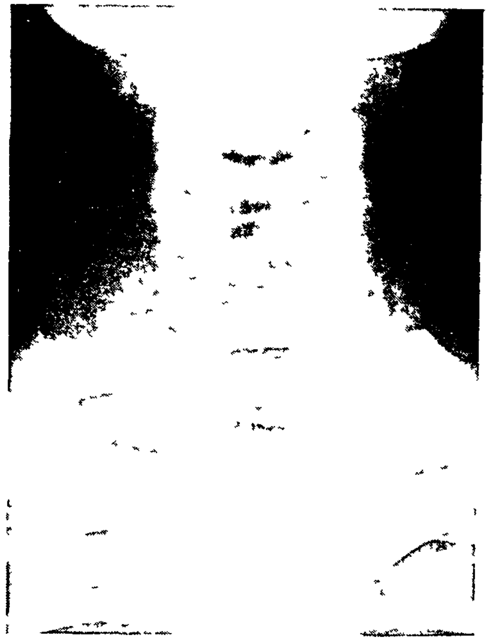

Fig 2—Injection into the jugular bulb in a cadaver with jugular veins compressed

The vertebral venous system is filled on both sides to the lower cervical level

the ventricular cavities" This misconception of rising ventricular pressure was encouraged by Dandy and Blackfan's (1914) theory that the rise in C S F pressure was caused by congestion of the choroid plexuses and increased fluid production in the ventricles Becht (1920) disproved this by showing that C S F pressure returned to its initial level within 11 seconds after release of jugular compression, but took 6 minutes to return after the volume of C S F was increased by the subarachnoid injection of saline

That venous and C S F pressures move in parallel was shown by Weed and Flexner (1921) in dogs, the fluid pressure increase bearing an almost constant relationship of 65% to the venous Bedford (1935) confirmed this In looking for the explanation of apparent anomalies in the results of Queckenstedt's test, attention must be focused on the changes attending intracranial venous distension as such, rather than those attending a rising C S F pressure in the ventricles, or elsewhere in the cranial cavity

Evidence for Posterior-fossa Obstruction by Queckenstedt's Test

After the introduction of ventricular puncture, some workers—e g , Gardner (1928) and Smyth and Henderson (1938)—sought to show that, on jugular compression, pressure rose higher in the ventricle than in the spinal canal if there was obstruction in the posterior fossa

O Connell (1943) drew attention to the fact that rise in pressure, measured through a wide-bore ventricular needle was much more rapid than through a narrow-gauge spinal needle, and that pressure rises in manometers connected to ventricular and spinal needles should not be directly compared

To eliminate this error, recordings were made of a series of combined ventricular and lumbar punctures, using a blunt fine-bore ventricular needle of the same gauge as the lumbar one Jugular, thoracic, and abdominal compression were successively performed, and manometer readings were recorded in the ventricle and spinal theca The series observed included some patients with normal intracranial pressure, and others with proven obstruction at the tentorium and aqueduct, or at the foramen magnum In none of these did the ventricular pressure rise higher or more rapidly than the lumbar pressure There was apparently some mechanism whereby pressure was equalised throughout the cerebrospinal axis even when the pathways were obstructed That this mechanism resides in the vertebral venous system is seen at surgical exposure of the posterior fossa

When jugular pressure is applied, there is a rapid outflow of C S F from the fourth ventricle, and the cerebellum is displaced downwards, but, in addition, there is distension of the whole venous bed in the posterior fossa and in the visible upper region of the cervical spinal canal Plainly, therefore, a rise in pressure caused by distending this venous bed will be transmitted to the C S F pathways whether there is obstruction at the tentorium and fourth ventricle or not Outflow of C S F from the fourth ventricle may be impeded, but displacement of venous blood into the cerebellar and spinal veins will not Obstruction in the posterior fossa may sometimes

delay the rise of fluid in a spinal manometer on jugular compression, but it will not prevent it.

Obstruction in the Cervical Canal

A negative Queckenstedt test in the presence of obstruction in the cervical C.S.F. pathways is less easily understood, but has often been described.

Symonds and Meadows (1937) analysed seven cases of tumour at and below the foramen magnum. In none was a complete manometric block demonstrated, although in four the rise or fall was described as being a little delayed. In the one case in which a satisfactory myelogram was obtained, complete spinal block was demonstrated. These workers were led to conclude that "the degree of subarachnoid block, in relation to the severity of the clinical symptoms, would appear to be less in these cases of high cervical tumour than it is at a lower level." It is more likely that the degree of subarachnoid block is as great, but the methods of detecting it are subject to error.

Martin and Kleyntjens (1950) described three lumbar punctures performed on cases of meningioma at the foramen magnum. Two showed a slow rise and fall of pressure, and one had normal responses to jugular compression. They said "Queckenstedt's test shows little, a complete block being quite exceptional."

Weinstein and Wechsler (1940) described a dermoid tumour in the foramen magnum in which the Queckenstedt responses were normal. Congenital deformities in this region may also cause spinal obstruction. Gustafson and Oldberg (1940) described four lumbar punctures in their series, two partially blocked and two without evidence of block.

List (1941) recorded five cases of platybasia, four partially blocked and one quite free as judged by spinal manometry. In the last case the spinal cord was reduced by pressure to a fibrous-looking band of small calibre.

I have observed seven cases of neurinoma or meningioma between C1 and C4 in which subarachnoid obstruction appeared to be complete at myelography or operation, although Queckenstedt's test was negative.

Experimental Evidence

It seemed likely that, as in the posterior fossa, the obstruction was being bypassed by transmission of increased venous pressure through the vertebral plexuses. Evidence in favour of this hypothesis was collected from venous-injection studies in man and animals.

A catheter was inserted into the internal jugular vein of patients undergoing carotid angiography. With both jugular veins occluded on the cardiac side of the catheter, injections of contrast material were made. Fig 1 shows the intracranial venous distension spreading into the internal and external vertebral venous plexuses as low as C6–7. Injections of barium and dye into the jugular veins of cadavers cephalad to the point of venous obstruction confirmed this. X-rays showed a similar filling of the vertebral venous system (fig 2), and the spinal canal was shown to be filled with dye as far as C7 (fig 3).

Similar injections were made in monkeys after tying all the jugular veins. X-rays showed the filling of the vertebral veins and the escape back to the innominate veins and the heart (fig 4). The cord and dura preparation shows that the vertebral venous plexus filling extended, as in the human subjects, to the level of the lower cervical spinal canal (fig 5).

Provided, therefore, that a cervical spinal tumour does not obstruct the extradural as well as the intradural spinal veins, jugular compression will cause distension of the vertebral venous plexus as low as C6–7, with compression of the theca below the obstruction and a rise in pressure at the lumbar manometer. This rise may not be as great as that normally produced by this distension plus the C.S.F. displaced from within the skull to the spinal canal and thence to the manometer, but it may be sufficient to deceive even an experienced observer. (And in the event,

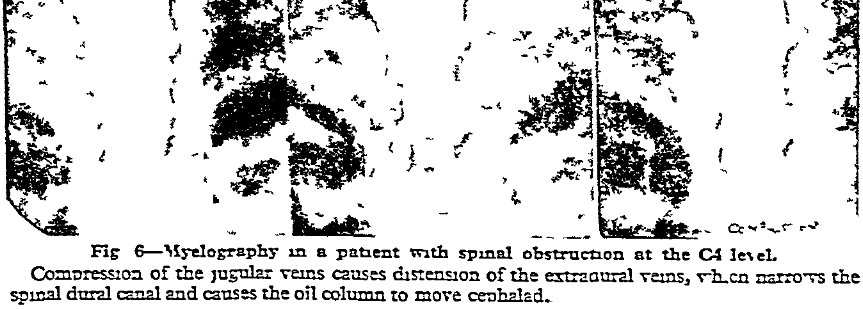

Fig 6—Myelography in a patient with spinal obstruction at the C4 level.

Compression of the jugular veins causes distension of the extradural veins, which narrows the spinal dural canal and causes the oil column to move cephalad.

most lumbar punctures are delegated to the inexperienced) This conception is very important for the understanding of C S F mechanics, because many theories about spinal pressures in Queckenstedt's test have been based on the elasticity or otherwise of the dura, which was presumed to be expanded by the increase of C S F, volume within If the theca is compressed from without in the presence of cervical spinal obstruction, it clearly does not matter whether the dura possesses elastic properties or not If pressure changes are transmitted past a spinal obstruction by extradural venous distension, myelography in such a case should show the oil column narrowing and moving cephalad on jugular compression Fig 6 shows that this does in fact occur

Discussion

The elaborations of Queckenstedt's test by combined puncture methods led to attention being concentrated on changing C S F pressures rather than changing venous pressures The realisation that C S F and venous pressures move in parallel did not help, because observers came to think in terms of increased ventricular pressure being transmitted via the aqueduct to the cisterna magna and the spinal canal in one continuous wave, with obstruction at any point halting the wave As a result, it has been suggested at different times that Queckenstedt's test could help in the diagnosis of aqueduct stenosis, acoustic neurinoma, foramen-magnum tumour, or obstruction of a ventriculocisternal (Torkildsen's) tube The above experiments have shown that it will do none of these things Nor is it a reliable test for cervical spinal obstruction above the level C5–6, unless the extradural as well as the intradural vertebral veins are completely obstructed by the agent compressing the spinal cord A negative Queckenstedt's test should not, therefore, be allowed to cloud clinical judgment in patients showing evidence of cervical spinal-cord compression above this level

Summary

The modifications of Queckenstedt's test are reviewed

Combined cisternal and spinal puncture methods tended to obscure the importance of venous distension as the primary cause of rising cerebrospinal-fluid pressures, as indicated by manometers

Clinical and experimental evidence shows that Queckenstedt's test is unreliable in detecting obstruction of the cerebrospinal-fluid pathways above the C6 level

ANTICONVULSANTS AS A FACTOR IN MEGALOBLASTIC ANÆMIA IN PREGNANCY

P B B GATENBY
M D Dubl, F R C P I, M R C P
VISITING PHYSICIAN, ROTUNDA HOSPITAL, DUBLIN,
PHYSICIAN, MEATH AND DR STEEVENS' HOSPITALS, DUBLIN,
PROFESSOR OF CLINICAL MEDICINE, TRINITY COLLEGE, DUBLIN

THERE have been many reports of megaloblastic anæmia induced by anticonvulsant drugs—an association first described by Badenoch in 1954 The relevant literature is well summarised by Hawkins and Meynell (1958) This anæmia has followed the administration of phenobarbitone and phenytoin, and also primidone In 1956, Girdwood and Lenman drew attention to the similarity in chemical structure between folic acid and these compounds They suggested that these drugs interfered with folic-acid metabolism This was confirmed to some extent by Chanarin et al (1958) who studied a patient in whom megaloblastic anæmia developed after primidone therapy They found that both the absorption and storage of folic acid in the tissues were normal and concluded that interference with tissue metabolism rather than deficiency of folic acid was the cause of the anæmia Recently a similar condition was described in a case treated with phenobarbitone (Chanarin et al 1960) Hawkins and Meynell (1958) investigated the incidence of macrocytic anæmia in large numbers of epileptics who were being maintained with these drugs, and found that this complication was rare Macrocytosis was common, however, in these patients, and 45% of those receiving phenobarbitone and phenytoin showed this feature This macrocytosis could be corrected with folic acid

Megabloblastic anæmia in pregnancy is now being recognised more often, and many reports have been analysed by Chanarin et al (1959) In the same paper, these workers produced evidence of a folic-acid deficiency in two-thirds of those nearing the end of their pregnancy, and in all patients with twin pregnancy All pregnant patients with megaloblastic anæmia were found to have a still greater deficiency of folic acid

Consideration of all these reports suggests that megaloblastic anæmia is more likely to develop when anticonvulsants are used in pregnancy Possible interference with folic-acid metabolism by these drugs is likely to increase the effect of the relative folic-acid deficiency which may occur in pregnancy Though Dimsdale (1959) drew attention to the danger of drug-induced megaloblastic anæmia in epileptics during pregnancy, no report of this complication has yet been found

In a recent survey of 100 cases of megaloblastic anæmia in pregnancy seen at the Rotunda Hospital (Gatenby and Lillie 1960), it was noted that 3 of the cases were epileptics receiving anticonvulsants The incidence of epilepsy in the general attendance at this hospital is approximately 1 in 400, so that the incidence of 3%

TABLE I—ANTICONVULSANTS AND MEGALOBLASTIC ANÆMIA IN PREGNANCY

Anticonvulsant drugs	Number of patients	Number of pregnancies	Incidence of megaloblastic anæmia
Phenobarbitone	28	48	0
Phenobarbitone and phenytoin	7	7	4*
Phenobarbitone and primidone	1	1	0
Methoin (Mesontoin)	1	1	0
No treatment	7	13	1
Total	44	70	5

* 1 unconfirmed

ngst the cases of megaloblastic anæmia suggested a ual relationship.

The records of all pregnancies in epileptics over a six- period (1953 to 1958 inclusive) were studied. 70 nces occurred in 44 epileptics. In 7 of them (13) no anticonvulsants were being adminis-, because there had been no attacks for many years. case of megaloblastic anæmia occurred in this group. The remaining cases were divided into groups depending on the anticonvulsants used. Table I shows the relative incidence of megaloblastic anæmia. There were no cases in 48 pregnancies treated with phenobarbitone alone. There were 4 cases (1 unconfirmed by bone-marrow biopsy) out of 7 treated with phenobarbitone combined with phenytoin.

In table II details are shown of the established cases. All had severe megaloblastic anæmia which responded briskly to folic acid by mouth, 20 mg. daily, in spite of continuation of the anticonvulsant treatment. Case C is noteworthy because phenobarbitone alone had been administered in previous pregnancies without the development of megaloblastic anæmia. None of these cases had achlorhydria. Cases A and B are still under observation and neither has shown radiological evidence of gastrointestinal abnormality.

TABLE II—MEGALOBLASTIC ANÆMIA IN PREGNANT EPILEPTICS RECEIVING PHENYTOIN

Case	Pregnancy	1st Hb estimation	Onset of anæmia	Hb at onset	Reticulocyte-peak with folic acid
A	2nd (no treatment during 1st)	11·1 g. per 100 ml. at 24th week	6 weeks antepartum	5·8 g. per 100 ml.	12% on 5th day
B	1st	8·1 g. per 100 ml. at 32nd week	4 weeks antepartum	4·3 g. per 100 ml.	14% on 6th day
C	6th (phenobarbitone during previous pregnancies)	12·4 g. per 100 ml. at 24th week	2 days antepartum	6·4 g. per 100 ml.	15% on 6th day

Summary and Conclusions

From this analysis, it appears that there is a high incidence (3 out of 7) of severe megaloblastic anæmia when phenytoin together with phenobarbitone is used in the treatment of epilepsy in pregnancy. It is recommended that, if phenytoin is being administered to an epileptic during pregnancy, either oral folic-acid supplements should be given during the last trimester, or frequent hæmoglobin estimations should be done to detect the onset of anæmia. If it proves to be megaloblastic, it will respond well to folic acid, the anticonvulsant treatment need not be interrupted.

The incidence of megaloblastic anæmia in 57 pregnancies in epileptics receiving anticonvulsant therapy was studied retrospectively. There were no cases in 48 pregnancies where phenobarbitone alone was used. In 7 pregnancies where phenytoin was used as well as phenobarbitone there were 4 cases (1 unconfirmed) of severe megaloblastic anæmia. Folic acid cured the anæmia in these cases, while allowing the anticonvulsant therapy to be continued.

I wish to thank Dr. E. W. L. Thompson, ex-Master of the Rotunda Hospital, for permission to publish this report of patients who were under his care. I am greatly indebted to Dr. H. C. Moore, pathologist, for his assistance.

HYPONATRÆMIA is associated with reduced osmotic activity in the extracellular fluid and may occur with lowered, normal, or increased body-sodium stores. It may follow sodium depletion, water retention, or reduction in cellular osmolarity (Schroeder 1949, Sims et al. 1950, Rapoport et al. 1951, Danowski et al. 1955). Renal handling of sodium is variable, and retention or abnormal urinary loss may occur (Rapoport et al. 1951, Schwartz et al. 1957, Orloff et al. 1959).

Hyponatræmia may be found in adrenal failure and severe cardiac, renal, or hepatic disease. It has been described in tuberculosis, cerebral disease, and diabetes, and after excessive loss of body secretions by any route (Danowski et al. 1955, Elkinton 1956).

It may develop during acute lobar pneumonia and tuberculosis (Atchley et al. 1923, Winkler and Crankshaw 1938, Sims et al. 1950). A patient with bronchial carcinoma who showed hyponatræmia and abnormal renal chloride loss was described by Winkler and Crankshaw (1938). Recently, Schwartz et al. (1957) reported two patients with carcinoma of the bronchus in whom hyponatræmia and renal sodium loss probably resulted from inappropriate secretion of antidiuretic hormone. We describe here a further patient with a bronchial neoplasm and hyponatræmia in whom this mechanism did not operate. As well as deficient sodium retention, he had aminoaciduria and increased phosphate excretion. The presence of an acquired renal tubular defect is suggested.

Case-record

A stoker, aged 53, was admitted to the Gordon Hospital on April 17, 1959. For two months he had suffered malaise, non-productive cough, and loss of appetite, with particular revulsion for sweet and starchy food. He had lost 17 lb., and in the previous fortnight had suffered from nausea, with vomiting on four occasions. During the same period he had noted cramps in the abdomen and legs.

He had had a dry mouth and increased thirst for a week before admission. On April 15, he had fainted, and had since been confined to bed. There was no disturbance of micturition, but he had been constipated for a fortnight. He had been a moderate pipe smoker for years, and took little alcohol.

Examination

He was thin and wasted There was no clinical dehydration or œdema No abnormal pigmentation was noted B P 100/60 mm Hg Respiratory system fine râles at bases of both lungs, otherwise normal The tongue was furred, but the mouth was not dry

Investigations

Daily serum-electrolyte and blood-urea levels, urine-volumes and electrolyte content, and fluid and sodium intakes are shown in table I and in figure

Blood —Hæmoglobin 15 0 g per 100 ml Erythrocyte-sedimentation rate (Wintrobe) 11 mm in the first hour Total white-cell count 9000 per c mm (neutrophils 70%, lymphocytes 30%) Liver-function tests, serum-amylase, and serum-cholesterol normal Serum-albumin 3 9 g per 100 ml Serum-globulin 2 5 g per 100 ml Random blood-sugar 123 mg per 100 ml Wassermann and Kahn tests negative Serum-alkali reserve (day 13) 24 mEq per litre Serum-alkaline phosphatase 7 King-Armstrong units Serum-calcium 10 6 mg per 100 ml , serum-inorganic phosphate 2 2 mg P per 100 ml (day 2) Serum-calcium 13 3 mg per 100 ml , serum-inorganic phosphate 1 6 mg P per 100 ml (day 14) Serum-creatinine 0 6 mg per 100 ml (day 14)

Urine —Urinary calcium 350 mg per 24 hours Urinary phosphate 480 mg P per 24 hours Urinary creatinine 450 mg per 24 hours (day 14) Urinary aldosterone excretion (Dr R V Brooks) 1 8 µg per day (day 16), 1 7 µg per day (day 17) (normal range 3–8 µg per day with a mean of 5 µg) Steroid excretion is shown in table II

The specific gravity was always within the range 1 010–1 026 No albuminuria Intermittent glycosuria and ketonuria There was no glycosuria after day 13, and no ketonuria after day 18 Paper chromatography of urine for aminoacids (Dr J H Wilkinson) showed (1) a large increase of alanine, glycine, glutamine, histidine, lysine, threonine, and γ-amino butyric acid, (2) a moderate increase of glutamic acid, taurine, and serine, (3) small quantities of valine, leucine, and tyrosine, and (4) traces of methyl histidine and cystine This pattern of generalised aminoaciduria was present up to the time of death

Sputum —No malignant cells

X-ray of chest —Mass in left lung near hilum, with bilateral hilar-gland enlargement Normal pulsation and diaphragmatic movement on fluoroscopy

Isotope studies (Dr J F Zilva, Dr J P Nicholson) —Total exchangeable sodium (day 12) 2540 mEq = 54 1 mEq per kg (normal range 37–56 mEq per kg) Total exchangeable potassium (day 12) 2530 mEq = 54 1 mEq per kg (normal range 37 5–64 mEq per kg) Na/K = 1 00 (normal range 0 69–0 95) Bromide-space (day 13) 15 9 litres = 340 ml per kg , (day 14) 16 3 litres = 359 ml per kg (normal range for his build 248–378 ml per kg)

Electrocardiography —Day 1, alternating atrial flutter and fibrillation Fast ventricular rate of about 150 beats per minute with both rhythms Day 5, sinus rhythm, rate 80 beats per minute Tracings otherwise normal

Progress

The history of recent cough and the X-ray findings suggested bronchial carcinoma Severe hyponatræmia (109 mEq per litre) was found on admission and was associated with abnormal renal sodium loss (79 mEq in second half of day 1)

He gradually became worse He was moderately thirsty but too ill to drink unless assisted During the first four days he took sweetened fruit drinks only, and he continued to refuse food throughout the rest of his illness

Adrenal failure caused by bilateral metastatic deposits seemed unlikely with a normal blood-urea, a low serum-potassium (3 4 mEq per litre, day 1), and no pigmentation His blood pressure (95–100/60 mm Hg) was low but this was due to tachycardia, and it rose on day 4 to 120/80, when the arrhythmia reverted to sinus rhythm, though the hyponatræmia persisted (107 mEq per litre) He was so ill that it seemed best to give extra salt and sodium-retaining hormones until more was known of his adrenal function On day 5, oral salt in cachets and intravenous saline were begun (table I and figure), and he was encouraged to drink more He cooperated readily and high intakes were achieved between days 6 and 11 He also took a total of 6 mg fludrocortisone between days 5 and 9 This potent salt-retainer was used to avoid confusion in estimations of urinary steroid excretion which were done at this time Fludrocortisone was stopped as soon as these results were known

With this therapy there was slight improvement, though he remained weak The serum-sodium rose only slowly, and continued to rise when fludrocortisone was discontinued on day 8 and sodium intake was increased Intensive sodium therapy was given up to day 11 by which time the serum-sodium level had risen only to 121 mEq per litre

Between days 12 and 16, water intake was reduced as much as possible to see if this would affect the renal sodium loss as in the cases of Schwartz et al (1957) Sodium supplements were continued, so that he also received 1140 ml fluid daily intravenously, and negative fluid balance was not, therefore, achieved In this period, with an intake of 228 mEq sodium daily, the serum-sodium level continued its slow rise to 132 mEq per litre From about day 12, his condition steadily worsened, with increasing back pain at the level of the lower part of the thoracic spine, and by day 17 he was very ill No more intravenous saline was given, but oral supplements were continued for another 2 days His fluid intake was about

1·5 litres daily. He became emaciated, and bronchopneumonia developed. Finally he lapsed into coma and became clinically dehydrated. There was a terminal rise in blood-urea levels, and the serum-sodium rose to a maximum of 142 mEq per litre on day 20, though it fell again the following day to 127 mEq. He died on day 22.

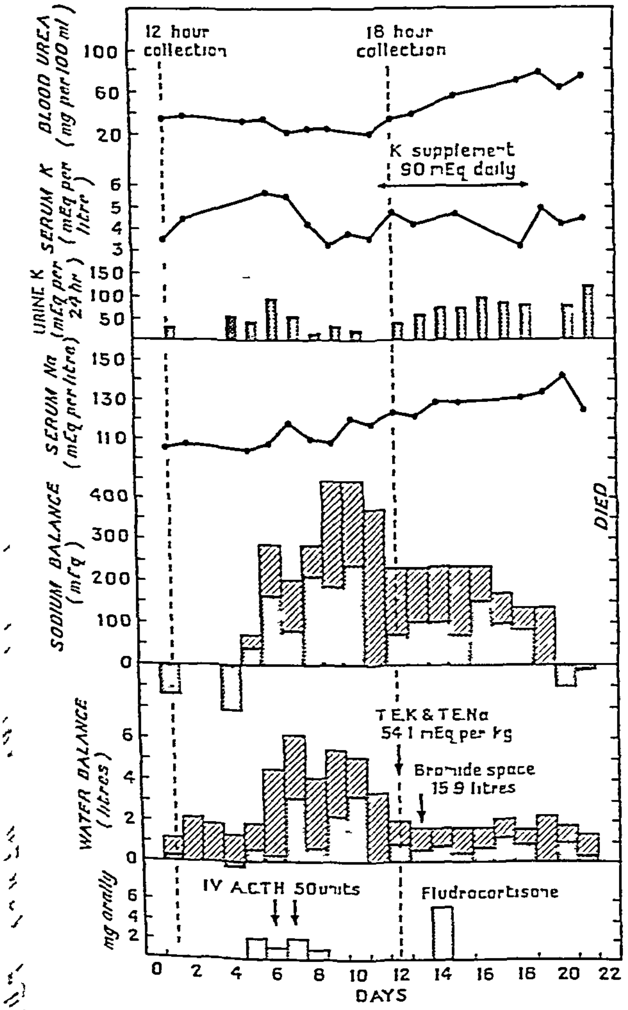
Necropsy

At necropsy (Dr J. S. Cornes) an oat-celled anaplastic carcinoma was discovered, originating in the lingular bronchus, and spreading to the lung, mediastinum, and left supraclavicular lymph-nodes. No other macroscopic spread was found, but histological examination showed infiltration of the liver and spleen by tumour cells.

The kidneys were macroscopically and histologically normal. Histochemical staining (Dr John Pryse-Davies) showed normal alkaline phosphatase, acid phosphatase, non-specific esterase, succinic dehydrogenase, and lactic dehydrogenase activity. Microdissection (Dr E. M. Darmady) revealed no abnormality.

The adrenals were enlarged (combined weight 22 g.) and histologically showed widening of the cortex principally in the zona fasciculata. Histochemical staining (Dr Pryse-Davies) for alkaline phosphatase, acid phosphatase, non-specific esterase, succinic dehydrogenase, and steroid 3-β-ol dehydrogenase suggested a hyperactive adrenal gland with increased steroid metabolism.

The parathyroids showed slight uniform enlargement. The pituitary contained a small developmental cyst, 3 mm. in diameter, but otherwise was normal.



Water and sodium balance calculated from intake and output figures with no allowance for extrarenal loss or water of metabolism.

Daily intake plotted up from baseline. Daily output plotted down from intake figures. Shaded areas above baseline represent positive balance, shaded areas below are negative balance. Intake data only for days, 2, 3, 11, and 19. For potassium, urinary figures only are shown. T.E.K. = total exchangeable potassium. T.E.Na = total exchangeable sodium.

TABLE II—URINARY STEROID EXCRETION

Day	Urinary steroids (mg per 24 hours)		Steroid therapy
	17-hydroxy-steroids	17-keto-steroids	
4	17·8	4·4	Nil
5	7·7	7·0	Fludrocortisone 2 mg. oral
6	66·0	16·8	Fludrocortisone 1 mg. oral Corticotrophin 50 units I.V.*
7	65·0	21·0	Fludrocortisone 2 mg. oral Corticotrophin 50 units I.V.
9	37·0	11·5	Nil
10	2·1	2·0	Nil
20	17·4	7·7	Nil
21	17·7	18·8	Nil

* I.V. = intravenous.

Discussion

The outstanding feature was the extreme hyponatræmia accompanied by malaise, cramps, and thirst. Mechanisms such as decreased cellular osmotic activity or a new steady state, which have been suggested to explain hyponatræmia in severe illness (Sims et al. 1950, Danowski et al. 1955) did not operate in our patient whose hyponatræmia improved as his clinical state deteriorated.

Addison's disease was not present, nor was there any evidence of the usual type of salt-wasting renal disease which is associated with obvious changes in the kidneys (Stanbury and Mahler 1959). The hyponatræmia was clearly associated, however, with deficient renal sodium retention. This is seen on day 1, and on day 4 when 108 mEq. sodium were excreted after at least 4 days without any salt intake. This sodium-leak was partially inhibited by fludrocortisone on day 5, but the presence of more than a trace of urinary sodium at this low serum-level (107 mEq. per litre) suggests that tubular response was impaired. By day 14, a large dose of fludrocortisone had no effect on sodium excretion showing that the tubular defect had increased.

Aldosterone excretion was reduced on days 16 and 17. By then massive sodium repletion had occurred. Extrapolating from the results on day 12 (allowing 10 mEq. daily for extrarenal loss), total exchangeable sodium is estimated at 2866 mEq. for day 16 (approximately 61 mEq. per kg.) and his serum-sodium had risen to a reasonable level for his clinical state. The low aldosterone excretion at this stage is therefore not surprising.

An estimate of the metabolic state on admission may be made from the isotope studies.

On day 13 the bromide-space was 15·9 litres (within normal limits), and before this marked positive water balance had occurred. Allowing 700 ml. daily as the balance between insensible loss and water of metabolism, a positive balance of 6·2 litres occurred between days 7 and 11. Unfortunately, the urine on day 11 was lost, but the intake makes a negative balance unlikely. Ignoring this day a positive balance of approximately 5·6 litres existed between days 5 and 13. Thus, on day 6, the extracellular fluid volume was estimated at 10·3 litres (about 220 ml. per kg.). This figure would have changed little from the time of his admission, and is abnormally low.

Total exchangeable sodium on day 12 was 2540 mEq. Ignoring day 11 again cumulative sodium retention from day 5 to day 12 was 972 mEq. The amount of food taken was negligible, and allowing 10 mEq per day for extrarenal sodium loss, the estimate for total exchangeable sodium on day 5 was, at most, 1640 mEq (approximately 35 mEq per kg)—an abnormally low figure Total exchangeable potassium on day 12 was 2540 mEq, and cumulative potassium loss in the previous week was 258 mEq (again ignoring day 11) Allowing 10 mEq daily for unmeasured potassium loss, the total exchangeable potassium on day 5 was estimated at about 2868 mEq (approximately 61 mEq per kg), which is in the upper normal range

Thus it appears that our patient on admission was depleted of sodium with a reduced extracellular-fluid space

In their two patients, Schwartz et al (1957) thought that carcinoma in some way caused inappropriate secretion of antidiuretic hormone This produced sodium loss by increased glomerular filtration and, because extracellular volume did not fall, by a failure of aldosterone secretion to rise with sodium depletion Both patients had severe hyponatræmia, in one case as low as 103 mEq per litre, with few symptoms In one the extracellular volume was measured, and was found to be raised

In our patient, the low estimate for extracellular space on admission makes it unlikely that inappropriate secretion of antidiuretic hormone caused his sodium loss The increased thirst in the week preceding admission is in keeping with this view, though thirst can occur with an increase in body water (Wynn and Rob 1954)

The effect of water restriction (days 12–16) was unimpressive There was no dramatic reduction in urinary sodium loss as in the patients of Schwartz et al (1957) and though restriction of water was not severe, it was more than was needed in one of their cases to reverse sodium loss Administration of large amounts of fluid caused improvement, rather than deterioration, and sodium given in this phase was largely retained in contrast to the results in their patients The poor response to salt-retaining hormones is a further point of distinction, and in addition our patient probably produced hypotonic urine on some days (e g, day 8, table I) when specific gravity was not recorded, whereas in the cases of Schwartz et al (1957) urine was hypertonic to plasma

In our patient, it seems that the renal sodium leak was due to impaired tubular function With liberal intakes, sodium loss was not excessive, and repletion was easily achieved However, when sodium intake was low, an obligatory renal salt-loss was revealed, leading to sodium depletion and, eventually, hyponatræmia

This defective reabsorption of sodium, together with intermittent ketonuria and glycosuria, suggested proximal tubular damage, and investigation led to the unusual finding of generalised aminoaciduria Other recognised causes of renal aminoaciduria were absent, and there was no evidence of the adult Fanconi syndrome (Wallis and Engle 1957) in which sodium loss, in particular, does not occur Overflow aminoaciduria may be found with increased protein breakdown, and since the plasma-aminoacid level was not estimated, this is a possibility in our patient, though other features favour its renal origin

Impaired phosphate reabsorption and low serum-phosphate levels accompanied the aminoaciduria, providing further evidence of proximal tubular damage The terminal hypercalcæmia and necropsy findings of parathyroid gland enlargement were probably due to secondary hyperparathyroidism

The distal tubular exchange mechanism of potassium for sodium could function normally as shown by falling sodium excretion in the last week, with increased potassium excretion and K/Na ratios, particularly evident on day 21 24-hour creatinine-clearance on day 14 was reduced, and rising blood-urea levels were recorded in the last week, indicating progressive reduction in glomerular filtration This might have reduced the load on the proximal tubules to a level at which they could function competently The resultant fall in distal tubular flow might then allow the efficient cation exchange and sodium conservation seen on day 21 A diminution in proximal tubular load would also explain the disappearance of glycosuria and ketonuria in the week before death

A defect in proximal tubular function was therefore thought to be present, and a similar defect was postulated by Rapoport et al (1957) as the cause of hyponatræmia in their patients with tuberculous meningitis However it remains difficult to explain the urinary composition on days 1 and 4 The metabolic state on admission should have resulted in maximal aldosterone secretion The modest potassium excretion and low urinary K/Na ratio at this time is surprising and, with the poor response to administered steroids, suggests that distal tubular function was also impaired

Summary

Severe hyponatræmia developed in a man of 53 with bronchial carcinoma He showed poor renal sodium conservation which, with negligible intake because of anorexia, had caused sodium depletion

Repletion was easily achieved and fluid restriction did not affect the sodium loss Metabolic studies suggested that, on admission, he was depleted of sodium, with a reduced extracellular-fluid volume

There was no evidence of adrenal failure, and at necropsy the adrenal glands were enlarged and showed signs of hyperactivity

The renal response to fludrocortisone and corticotrophin was poor There was no clinical evidence of any of the usual types of salt-wasting renal disease, and at necropsy the kidneys were normal on detailed histological examination

There was evidence of functional damage to the proximal tubules with generalised aminoaciduria, glycosuria, ketonuria, and increased phosphate excretion Aminoaciduria was constant throughout, but glycosuria and ketonuria were intermittent and disappeared in the last week

The distal tubular exchange of sodium for potassium was active terminally, though perhaps not on admission It is suggested that the sodium loss was mainly due to proximal tubular damage, and that the bronchial carcinoma had caused this unusual derangement of tubular function

We wish to thank Dr R D Tonkin, under whose care this patient was admitted, for permission to report this case, and Dr R I S Bayliss for advice on the manuscript The microdissection of th kidneys was carried out by Dr E M Darmady The urinary amino-acid determinations were performed by Dr J H Wilkinson We are indebted to Dr R V Brooks for the urinary aldosterone assays Details of the adrenal and renal histochemical studies were kindly provided by Dr John Pryse-Davies The results of the isotope studies were provided by Dr J F Zilva and Dr J P Nicholson The necropsy was performed by Dr J S Cornes The figure was prepared by the department of medical illustration, Guy's Hospital

POSTPARTUM PRE-ECLAMPSIA

I R McFADYEN
M B Glasg
FLIGHT LIEUTENANT, R A F
From the Royal Air Force Hospital, Aden

A WOMAN, aged 19, had an eclamptic fit fifteen hours after she had her first baby She had given no evidence of pre-eclamptic toxæmia while pregnant, or during her eight-hour labour An episiotomy was necessary for delivery, and, in the course of its repair, she seemed drowsier than would have been expected from the 100 mg pethidine and the gas-and-air analgesia she had received during labour That night she slept uneasily, complaining of epigastric discomfort, and at 6 A M next day her blood-pressure (B P) was 140/90 mm Hg an hour later she had the fit

The patient was first seen during the sixteenth week of pregnancy No history of serious illness, previous pregnancy, or fits was given (this was confirmed in the puerperium) Her general condition was excellent Hæmoglobin 87% (Haldane), blood-group B, rhesus-positive, Kahn-negative The B P was 130/70, weight 105 lb , and her urine showed no abnormality Thirteen visits were made during the pregnancy Apart from a trace of albumin in a morning specimen of urine at the thirty-seventh week, and slight swelling of the ankles the week before that, the only abnormality of the pregnancy was a degree of hydramnios at the thirtieth week sufficient to warrant an X-ray of the abdomen The hydramnios decreased slowly but was still present at term The weight rose gradually to 128 lb at term, and fell 1 lb in the following week The blood-pressure remained between 110/60 and 120/80 during the pregnancy

Progress

Day 1 —A healthy 6½ lb infant, born ten days after the estimated delivery date The labour was uneventful Total blood loss 8 oz , 0 5 mg of ergometrine was given intramuscularly after delivery of the placenta

Day 2 —B P after the fit, 140/90 There was no residual paralysis, but facial œdema was noted and this increased during the next few hours The patient was sedated with barbiturates, and given a low-salt diet During the day her B P remained at about 130/90 Morphine was given that night as she complained of headache

Day 3 —The B P fell until it was 125/80 in the evening, the œdema subsided, and the patient had no complaints

Day 4 —About seventy-two hours after delivery the frontal headache and facial œdema returned The breasts became engorged and treatment for the suppression of lactation was begun Her temperature rose until it was 102 6°F by the evening She was moved into an air-conditioned room, and sedated with 6 g amylobarbitone six-hourly and 25 mg chlorpromazine orally twice daily The hæmoglobin was 88% (Haldane) and the hæmotocrit value 40%

Day 5 —A morning catheter specimen of urine contained 200 mg albumin per 100 ml , 15–25 red blood corpuscles, and 3–4 white corpuscles per high power-field, it was sterile A Foley catheter was introduced and nitrofurantoin 100 mg given six-hourly to prevent a urinary infection She passed 1290 ml of urine that day The œdema and headaches remained The temperature fell to 98 4° by the evening The blood-pressure, however, started to rise during the day

Day 6 —The B P continued to rise until in the evening it reached 170/100 At that point 12 5 mg hydrallazine was given orally this was followed an hour later by a fall in B P to 145/100 The dose was increased by stages to 37 5 mg four-hourly The B P fell gradually, until on the tenth day it was consistently 130/80 at the time that the next dose was due

The typical pre-eclamptic facies and headache remained until the sixth day when, along with the albuminuria, they started to subside On the ninth day the catheter was withdrawn, the administration of chlorpromazine was stopped, and the patient was moved out of the air-conditioned room The output of urine did not fall below 950 ml per twenty-four hours, nor did the blood-urea rise above 20 mg per 100 ml and the blood-electrolytes remained within normal limits

The hydrallazine was continued until the fifteenth puerperal day It was gradually reduced thereafter, and was stopped on the twentieth day The B P had then been 105/75 for three days, there was an occasional trace of albuminuria, and the patient had no symptoms The baby was bottle-fed and thriving

Six weeks after delivery the patient was seen at the postnatal clinic She had suffered no headaches or swelling of the ankles since leaving the hospital, nor were there any other complaints The urine contained no albumin, the B P was 110/75, and she weighed 106 lb Uterine involution was satisfactory

Discussion

Stander et al (1946) described 21 cases of eclampsia occurring within thirty hours of delivery 13 of these had shown no evidence of antepartum pre-eclamptic toxæmia In 9 cases of postpartum convulsions in the first twenty-four hours of the puerperium published by Hofmeister and Brown (1953), 2 had given no previous signs of pre-eclampsia Theobald (1955) quotes 4 cases of antenatal eclampsia in patients known to have been normal at some time in the twenty-four hours before the fits It is clear that this fulminating eclampsia can also occur in the puerperium It is not, however, common for a patient to develop the pre-eclamptic syndrome for the first time after delivery and after a fit, in none of these series is it mentioned Hamilton (1953) states that hypertension and convulsions may be produced by intravenous ergometrine given at the time of delivery, but this is not accompanied by œdema and albuminuria, and the blood-pressure usually settles within four hours

There is a school of thought which holds that pre-eclamptic toxæmia and eclampsia are due to increased myometrial tension, pointing out that twins and hydatidiform moles are examples of an overdistended uterus being frequently associated with pre-eclampsia Theobald (1955) gives as one of his essential criteria for any hypothesis purporting to explain the genesis of eclampsia that it must afford a reasonable explanation of eclampsia occurring up to four days after delivery of the placenta, and many find this a stumbling-block in accepting this hypothesis

A possible explanation of my case can be obtained from the concept of pregnancy as "a kind of physiological Cushing's syndrome" propounded by J S L Browne and elaborated by F J Browne (1958) In this it is held that the adrenal cortex undergoes hyperplasia in pregnancy under the influence of the large quantities of corticotrophin produced by the hypertrophied anterior pituitary and the placenta, and Poideven's (1959) demonstration of the relationship of striæ gravidarum to adrenal cortical hyperfunction supports it The excess of corticosteroids produced has been demonstrated by Gemzell (1953) who

found that in the last three months of normal pregnancy the blood level of 17-hydroxycorticosteroids is four times the normal non-pregnant value. This would produce œdema and hypertension were it not that the healthy placenta inactivates the excess of pressor substance. If, however, placental function is diminished below some critical value by placental ischæmia (as may occur in essential hypertension, in a primigravid uterus which has hypoplastic vessels, or in twin pregnancy) pre-eclampsia develops. The same investigator has also shown that immediately after delivery the corticosteroid level is seven times the normal, but that it falls to the non-pregnant level by the sixth puerperal day. It might be expected that this would produce hypertension as the placenta is no longer present. This, in fact, happens. Browne (1958) quotes findings, in Sydney and London, that 20–30% of women whose blood-pressure remains within normal limits throughout pregnancy and labour are hypertensive in the first three days after delivery.

I have recently seen two patients in whom the pre-eclamptic syndrome developed after normal pregnancies; a third patient developed hypertension after a forceps delivery, during which she received two doses of 0·5 mg. ergometrine each.

Case 1.—A patient, whose first pregnancy and puerperium were quite uneventful, delivered her second child after a three-and-a-half-hour labour at term, and was given 0·5 mg. ergometrine intramuscularly. Antenatally her B.P. had not risen above 125/75, nor was there any other abnormality. One and a half hours after delivery she vomited and complained of headache. Her B.P. was then 180/110. She was sedated with morphine. Six hours later the headache was still present and she had developed generalised œdema with typical pre-eclamptic facies. The B.P. was 155/100, and a swab specimen of urine contained albumin ++. Sedation was continued and the œdema gradually settled. Thirty-six hours after delivery the headache and œdema had disappeared, the B.P. was 125/85, but there was still albuminuria. Thereafter the puerperium continued normally. The patient was discharged on the tenth puerperal day, her B.P. being 130/80, and the urine contained a trace of albumin.

Case 2.—Normal labour after a second uneventful pregnancy. A single intramuscular dose of ergometrine was given after delivery. On the third day of the puerperium the patient developed headache, hypertension (155/100), and gross generalised œdema. These increased in severity on the fourth day and then responded to rest in bed, sedation, and chlorothiazide therapy. She left hospital on the twelfth day, but the œdema recurred when she was at home and did not disappear for some weeks. The patient was a midwife, and remembered a similar sequence of events after her first confinement.

Case 3.—A primigravida with an uneventful antenatal course, the highest B.P. reading being 130/65. After a twenty-five-hour labour she was delivered with forceps under pudendal block anæsthesia, because of second-stage delay. Ergometrine 0·5 mg. was given with delivery of the anterior shoulder. As the uterus tended to relax an intramuscular dose of 0·5 mg. ergometrine was given. One hour and fifty minutes after delivery she complained of nausea; the B.P. was then 170/105. The patient was sedated with amylobarbitone. The B.P. fell steadily: four hours after delivery it was 135/80, and it did not rise again. There was no œdema.

The development of the pre-eclamptic syndrome after emptying of the uterus in the first two of these cases could easily be interpreted in terms of the foregoing hypothesis. A similar transient hypertension to that occurring in the third case was noted after a cæsarean section where the patient also had a double dose of ergometrine, and it is probable that the rise in blood-pressure was caused by the ergometrine in both cases.

Summary

A case of postpartum pre-eclampsia with one eclamptic fit is described in a patient who had hydramnios but no pre-eclamptic toxæmia before delivery.

A possible explanation is that the already high blood-levels of 17-hydroxycorticosteroids during the last three months of pregnancy rise still more immediately after delivery, and do not fall to normal until the sixth puerperal day. Pre-eclampsia will occur in this period if, through ischæmia, placental function is reduced below some critical value. Postpartum pre-eclampsia may arise once the placenta is delivered, because the excess of pressor substance is then no longer inactivated, and hypertension and œdema result.

I wish to thank Dr. J. B. Hewitt for his encouragement in the preparation of this paper, and the Director General of Medical Services, Royal Air Force, for permission to publish.

Preliminary Communication

HYALINE MEMBRANE FOLLOWING TOTAL BODY RADIATION

RELATION TO LUNG PLASMINOGEN ACTIVATOR

In 1940 Warren and Spencer[1] pointed out that hyaline membrane formation was the most definite of all changes produced in the lung by X-irradiation of the chest. These changes were observed after "chest wall doses" of 800–15,000 r. Though hyaline membrane was by no means pathognomonic of irradiation lung damage, its association with œdema, fibrosis, diminished inflammatory response, and hyalinisation of arterial walls was sufficiently unusual to enable irradiated lung to be distinguished from the non-irradiated. The pathogenesis of this lesion is not understood.[2]

Recently patients with far-advanced malignancies have been subjected to total body radiation (T.B.R.) at the National Naval Medical Center, utilising a $4\pi\ ^{60}$Co irradiator.[3] Clinical results are to be described elsewhere, but we wish to report that at necropsy hyaline membrane and fibrinoid deposits have been prominent in cases surviving at least two weeks after treatment.

Lieberman[4] has recently associated hyaline-membrane disease of children with deficiency of plasminogen activator in the lung. This tissue enzyme converts plasminogen to plasmin, the active fibrinolytic enzyme of the body. Lung normally contains high levels of plasminogen activator.[4,5] Lieberman reasons that because of the relative insolubility of lung plasminogen activator its action is primarily local. In situations where there may be a pathological deposition of fibrin in the lung, it would

* Assayed for inhibitor—all positive.

be the activator's function to activate the fibrinolytic system and effect the fibrin's removal. Persistence of fibrin deposits due to a defect in this system would lead to hyaline-membrane formation[4] and fibrosis.

The fibrin-plate technique of Astrup as outlined by Lieberman[4] was utilised and in addition fortified with 0·01 M Ca ions. The latter are added to saturate the citrate of commercial bovine fibrinogen and obviate non-enzymatic lysis of the fibrin.[5] This technique is considered quite sensitive and specific for the detection of plasminogen activator.[7]

OBSERVATIONS

Lieberman[4] has well documented the presence of activator in normal adult lung and this has been confirmed by us in a case of traumatic death. Two men who had undergone T.B.R. therapy were investigated. One had received 450r T.B.R. for disseminated lung cancer 18 days before death, and the other 1500r T.B.R. 15 days before death. The latter had no associated malignancy and had been treated in conjunction with an attempted transplant of kidney. In both instances hyaline membrane was present in the lung. Intensity of membrane formation has generally been associated with high dosage and survival for more than 6–8 weeks after therapy.[6] In both cases the assay of lung tissue failed to demonstrate any plasminogen activator.

To follow the sequence of events eleven dogs were subjected to T.B.R. in similar fashion to the human subjects. The table shows the results of assays of lung activator at various intervals in these eleven dogs and in ten controls.

The absence of activator in the irradiated animals could be due to inhibition. Portions of lungs from three animals with absence of activator were homogenised and the homogenate was mixed with equal volumes of an active lung homogenate. In each case the activity of the normal lung was completely inhibited. The animals tested are indicated in the table by an asterisk.

None of the lung sections showed the classical signs of radiation lung damage, and often they were described as normal. Since several weeks are generally required for the development of hyaline membrane,[6] and the animals in this dose range of T.B.R. seldom survive beyond the second week, this finding might be expected.

COMMENT

In two men treated by total body radiation hyaline membrane was found in the lung. Plasminogen activator was apparently absent.

The enzyme soon disappeared from the lungs of dogs given T.B.R. of 800–1000r, but these showed no morphologic change suggestive of the first stage of either hyaline membrane or fibrosis.

Our findings are consistent with the production in irradiated lung of a potent inhibitor of plasminogen activation.

Further studies are in progress to assess the influence of drugs and radiation technique on the activator system in the lung.

The opinions expressed in this paper are those of the authors and not necessarily those of the Navy Department.

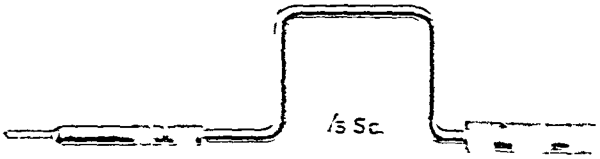
A BRACE SCREWDRIVER

ALTHOUGH Fitzgerald described a brace screwdriver several years ago[1] this has never become popular, and the ease with which screws can be inserted by its use has not been generally appreciated.

Repeated gripping of a conventional screwdriver and pronating and supinating the forearm, can be very tiring—as many as 150 repetitions of this movement being necessary to insert four screws. The brace screwdriver, by its continuous action, removes this strain and also eliminates the inertia of the screw which develops each time it stops turning. The lessened resistance diminishes the chance of the screw breaking and the brace gives better control.



The type of brace is important. The model here illustrated, adapted from a socket spanner, can be held firmly along the axis of the screw. There should be no sleeve on the crank handle so that the hand can appreciate small changes in resistance during insertion. Some screw-holding attachment is essential. A simple holding sleeve, made by the London Splint Co. for one of their conventional screwdrivers, was used at first and proved quite satisfactory. The Williams screw-holding device, made by Chas. F. Thackray Ltd., although more elaborate, could also be used for this purpose. The brace here illustrated uses the Stryker screw-holding attachment. The Stryker attachment was devised for a power-driven continuously rotating screwdriver, and it is particularly suited to the rotary action of the brace. It has the great advantage over any other screw-holding attachments that the chuck not only releases the screw head automatically but also allows the screw to be fully driven home and tightened by one continuous action, thereby avoiding the need to complete the last few turns with a conventional screwdriver.

This final pattern of brace screwdriver is available from Messrs. Down Bros. Ltd., 21 St. Thomas Street, London S.E.1. By its use screws can be inserted into the upper femur with appreciably greater speed and precision than by any previously available hand-driven device.

Reviews of Books

The Problem of Acute Hypothermia

Editor P M STARKOV Translated from the Russian by R E HAMMOND Editor of English edition E NEIL, M D, professor of physiology, Middlesex Hospital Medical School London Pergamon Press 1960 Pp 329 70s

THIS book contains the results of many years research in Professor Starkov's department in Omsk There are twenty-eight articles by the fourteen workers concerned, and they are all physiological, though the hope is expressed that some of the conclusions may be put to practical use The subject titles alone make interesting reading, for, as might be expected, they imply a quite different approach to the physiology of hypothermia from that in the Western world, where much of the work has been planned pragmatically, according to the needs and problems of the operating-theatre, and not so much concern, perhaps, is felt about the basic differences between the body functions at normal temperature and those revealed during hypothermia Physiologists will therefore welcome the results of study on such fundamentals as cold effects on blood-flow in limbs and viscera, on the effects of direct cerebral cooling, and the use in hypothermia investigation of the values accorded by such familiar parameters as those of the heart-lung preparation, decerebrate cat, isolated rat uterus, and skeletal muscle Behaviour and conditioned reflexes in puppies and adult dogs are subjects of natural interest to Russian physiologists, and the response of these nervous patterns to hypothermia is the subject of one of Professor Starkov's own articles

The publishers regret that for speed and economy of production the text is in typescript photolithography, but the quality of the pages is even and good, and the content more than makes up for any deficiency The translation is commendably clear

Lectures on Hæmatology

Editor F J G HAYHOE, M D, M R C P, department of medicine, University of Cambridge London Cambridge University Press 1960 Pp 247 60s

THESE lectures were delivered at Cambridge in December, 1959, at a course for physicians and clinical pathologists "having hæmatology as one of their main interests" Four of these lectures will interest any hæmatologist J V Dacie gives some facts from his unique experience in hæmolytic anæmia, W M Davidson provides an excellent account of iron metabolism and treatment, G Wetherley-Mein describes interestingly and practically what is meant by "myeloproliferative syndromes", and R M Hardisty makes a gallant attempt to bring together in a moderately coherent account what we now know about hæmostatic processes The other lectures are good, sometimes very good, reporting work that will be familiar to many hæmatologists R H Girdwood on megaloblastic anæmias, George Discombe on transfusion hazards, and J C White on hæmoglobin variants summarise their already published work Dr Hayhoe himself draws on some pages from his recent book on leukæmia Richard Doll writes on the incidence of leukæmia and the significance of environmental factors, D A G Galton on the chemotherapy of leukæmia, G I C Ingram on congenital and acquired disorders of blood coagulation, and J F Ackroyd on the pathogenesis of purpura H E M Kay brings together a useful summary of published results on attempts to use marrow transplants in the treatment of leukæmia

This sort of book falls between two stools the specialist in hæmatology will be interested only in the first four lectures we mentioned, the more general physician or pathologist with a main interest in hæmatology will hardly wish to buy a set of lectures that will need revision in a short time, especially when he can buy a whole textbook of hæmatology, containing nearly everything in this volume and a lot more, for rather less This volume is to be one of a series why not publish the others in a less expensive form—say, paper back with plastic binding and without some of the illustrations, none of which, in this hæmatology volume, are really necessary ?

Chemical Micromethods in Clinical Medicine

R H WILKINSON, M D, assistant chemical pathologist, The Hospital for Sick Children, London Oxford Blackwell Scientific Publications 1960 Pp 121 40s

EMPHASIS on micromethods in chemical pathology has increased steadily during the past twenty years It was gradually realised that blood-sugar and blood-urea were not the only substances that could be measured using capillary blood and that it was obviously more considerate and convenient to take small samples of capillary blood by needle-prick than larger ones from a vein by syringe It has also become clear that small amounts of heparinised blood may yield as much plasma as larger amounts of clotted blood can yield serum These considerations apply particularly to pædiatrics, and in this country notable contributions to microchemical methods have come from The Hospital for Sick Children, Great Ormond Street, and some very important ones from the author of this little book There are only about 100 pages of text, of which 10 are taken up by illustrations, not all of them essential (a page is used for a photograph of a Van Slyke manometer and another for its micro version, and almost a whole page is given to a photograph of the EEL flame photometer, which has been in routine use in virtually all pathology laboratories for many years) Most of the methods for examining blood in a pædiatric hospital are clearly described (the estimation of serum-iron is not among them) Micromethods only are considered, and this excludes many important pædiatric investigations of urine and fæces

Principles of Animal Virology (2nd ed New York and London Academic Press 1960 Pp 490 86s)—This book, edited by Sir Macfarlane Burnet, O M, F R S, is very different from Burnet and Stanley's *The Viruses*,[1] and is much more concerned with viruses of men and animals as agents of disease A particularly interesting aspect is its emphasis on the ecology of viruses and on evolutionary aspects of virus development Much of the book is written from a very personal viewpoint, and the references are selective rather than comprehensive Nearly half the text of the first edition, which appeared five years ago, has been rewritten

Preventive Medicine and Public Health (4th ed London H K Lewis 1960 Pp 316 27s 6d)—It is no easy matter in these days to write a universally acceptable student textbook on public health, there is still so much diversity of opinion about the legitimate scope of the subject and so much variation from school to school in attention given to it Prof Fred Grundy's book aims to be an introduction for students and practitioners and it obviously meets a want, for it is now in its fourth edition in ten years The book is necessarily simple in its approach, and some of its pictures could perhaps be shed without much loss, but it does provide an outline of basic principles and for the zealous it offers suggestions for further reading

Hypnoanalysis (New York Grove Press London John Calder 1960 Pp 342 16s 6d)—Dr Lewis R Wolberg's wide experience of hypnosis is well known, and some of his writings have become classics This paperback, which is a reprint of a 1945 Grune & Stratton edition, is devoted to the use of hypnotic techniques during psychoanalysis, in this case Freudian The first 136 pages describe the treatment of one patient, then follows a 21-page "dynamic formulation" by Dr A Kardiner, and in the final 179 pages Dr Wolberg suggests the various ways in which hypnosis can be of use in psychoanalytic treatment The case-report is certainly of great interest, notwithstanding the doubt in diagnosis, and Dr Wolberg writes better than most analysts, but the work will do little to convince the sceptical Practitioners who use either of these techniques will find the book interesting, but there must be serious reservations about presenting this new edition to the large lay readership for which it is presumably intended

Coming Home and Going Abroad

On achieving independence, a Colony naturally wants to have all its services manned by its own people, and that is something to which every new nation should look forward But commonly the wellbeing and progress of Colonies have depended largely on the devoted work of administrative and professional officers from overseas, and usually these ought to go on with that work until there are enough properly qualified indigenous officers to replace them Unfortunately the insecurity of a new regime may lead to an exodus of many of the men and women whom the new country will most need in the next few years The anxieties of a Civil Servant in a country likely to become self-governing are well depicted in the white-paper [1] issued last week

> " the sense of vocation which led him into the Public Service in an overseas territory still remains, but he is beset by uncertainty as to the extent to which he will be able to fulfil it under the new conditions his status in public affairs is changing and very often he and perhaps his family also are subject to discomforts stemming naturally from a period of rapid political change, and until reassurance is given him on the shape of his future he must live through a period of extreme doubt about the years ahead "

To prevent the " tragic waste of human skills and wisdom " inevitable where a service runs down through departure of its key members, the British Government, as announced last July,[2] are offering ten-year agreements to most Colonial territories by which the territory need pay little more to employ someone from overseas than to employ one of its own nationals [3] In respect of some 21,000 officers of the Overseas Civil Service (appointed by the Colonial Office or the Crown Agents) the Government will be responsible (1) for the expatriation or inducement element often added to basic salaries to attract overseas candidates, (2) for the corresponding part of the pension, (3) for education and children's allowances, (4) for half the cost of leave passages, and (5) for half the cost of compensation payable for premature retirement While this excellent scheme can be looked on as an act of justice towards people who have been encouraged to take overseas appointments under the Crown, it is also much more It is an important offer of assistance, during the transition period, to territories which may see the advantages of retaining expatriate officers but might otherwise be unable to keep them The cost to Britain is estimated at between £12 million and £16 million a year

Two years ago at the British Medical Association's conference on overseas appointments,[4] one speaker said bluntly that if men are expected to go and work in the Colonial Service, arrangements must be made for them when they come back An attractive suggestion which is firmly turned down in an appendix to the white-paper is that the Civil Services at home and abroad should be unified, so that members could expect a full career, if not in the Colonies then at home But in point of fact the home Civil Service, with an administrative staff of less than 2500, can offer comparatively few openings to men returning from abroad, and the vacancies now likely to be offered to such men by other Colonies will usually be in a basic grade, and for only one or two tours of service The creation of a unified service based on the United Kingdom would, it is felt, give a false impression, because it could create no jobs for which members of the Overseas Civil Service are not already eligible Though some of these will enter the home Civil Service, or the Foreign Service, or may be assigned to other countries under technical-assistance agreements or similar arrangements, they cannot be sure of such employment, and for this reason the Colonial Office in July, 1957, set up an Overseas Services Resettlement Bureau to find them, if need be, alternative posts Of 1710 applicants the bureau has so far found employment for over 1000—about 500 of them in the past year The Government hope that " the knowledge that the Bureau will be there to assist them when required will both encourage officers to continue their overseas service, and new recruits to join it "

To the returning doctor even less than to the administrator can the Government guarantee a post at home, and latterly the difficulty of getting one has been a misfortune both to those who applied and to the public which has often been denied their services The Government's own medical establishment is small and specialised, and the Ministry of Health, even when it accepts a moral obligation to get a particular specialist appointed or reappointed to the National Health Service, finds regional hospital boards properly reluctant to choose anyone other than the best applicant for the job If the specialist has difficulty in establishing himself in this country, the difficulty can be even greater for general-duty officers who, though they may have been doing general practice at a high level, have usually been unable to secure National Health Service practices against the competition of younger men who have stayed here The gloom over our failure to reabsorb so many of our able people who have had the courage and enterprise to work abroad was epitomised in the statement of a speaker, two years ago, that he could not see how general-duty medical officers returning from Colonial service can fit in anywhere at any level in our medical services And this gloom seems as inspissated as ever, causing even the most sanguine to speak of this problem of medical resettlement as largely insoluble But are we not in fact dealing with a hangover rather than an incurable illness? If, as LAFITTE and SQUIRE [5] say, this country is shortly going to wake up and find

[5] Lafitte F Squire J R. *ibid* Sept. 3, 1960 p 538

Similarly the apparent risks of going abroad for a few years, on secondment or otherwise, may begin to bulk less large in the minds of candidates The Government are in favour of secondment from their own services here, and propose to have talks with representative bodies of employers " to seek their agreement to releasing staff on loan "—paying " in appropriate cases the differential between the terms of the overseas appointment and the local salary " If there are still senior members of the profession who are inclined to discourage their juniors from going abroad, we hope they will give thought to the white-paper's correct statement that service overseas affords " opportunities to do interesting work in a new environment, opportunities to exercise individual initiative and responsibility at an earlier age than is usual here, opportunities to develop personal qualities of self-reliance, leadership and adaptability arising from the wide variety of tasks to be undertaken opportunities to make an individual contribution to the development of a new country " Even more, perhaps, we hope they will read the remarkable review of the African situation, by Dr H S GEAR, which we publish this week Though GEAR credits colonialism with having given Africa a phase of social stability with a rising economy, and recognises that the main medical contribution has been, and still is, made by the official services, he is concerned mainly with the unofficial aspects of a system which hitherto has been continually nourished and refreshed from Europe " Medicine's true teachers and disciples give more to Africa," he says, " than medical care in a hospital or clinic ", and Western medicine should not overlook the need for this broader interpretation of its possible service " It should guide Africa to create people who are good doctors and nurses, but are also prepared to follow fearlessly the principles founded over many difficult generations in Europe and America "

Protein in Hyaline Membrane

THE chief component of the hyaline membrane found on histological examination of the lungs of premature infants who have died shortly after birth was once believed to be inspissated material derived from the amniotic fluid or vernix caseosa, and the term " vernix membrane " was used for some years[1] It now seems that a fundamental disorder of the pulmonary circulation plays a part in the formation of the membrane,[2] protein being extravasated from the pulmonary vessels into the neighbouring air-spaces and then forced by inspiration into a membrane lining the walls of these spaces

While most agree that the bulk of the membrane is composed of protein, there is still some difference of opinion as to its origin and nature LYNCH[3,4] initially suggested that the membrane represented a dried and concentrated secretion of the respiratory bronchioles and alveolar ducts Further work indicated that the membrane included hæmoglobin,[5] but the bulk of it was composed of fibrin[6,7] All these investigations reinforced the idea that the components of the membrane were derived from the blood-stream The various cardiovascular factors associated with hyaline-membrane formation were analysed by SHANKLIN[8] in a series of 335 premature infants He found that membrane formation was significantly more frequent in association with cardiac malformation that increased the pulmonary blood-flow The stages of the development of the pulmonary lesion were thought to be increased pulmonary blood-flow, left ventricular failure, pulmonary œdema, and membrane formation The possibility that maternal factors may play a part in the presumed circulatory disturbance has been investigated by COHEN et al,[9] whose work seems to indicate that membrane formation is commoner when the pregnancy has been complicated by toxæmia and especially by antepartum hæmorrhage From time to time it has been claimed that the frequency of hyaline membrane is increased in infants delivered by cæsarean section[10], but COHEN et al conclude that any such increase is limited to pregnancies where bleeding has occurred before delivery

The composition of hyaline membrane has been investigated by BUCKINGHAM and SOMMERS[11] They regard the structure as laminated acellular layers of eosinophilic material apposed to the walls of alveolar ducts, alveoli, and terminal bronchioles Ultraviolet microscopy showed that the material closely resembled plasma-protein or cell cytoplasm, in addition, some nucleoprotein was thought to be present Membranes produced experimentally by exposure of mice to oxygen had a similar composition The membranes thus seemed to comprise cytoplasmic material, hæmoglobin, polymerised fibrin, nucleoprotein, and mucoprotein These workers were impressed by degenerative changes in the bronchiolar epithelium, which they believe contribute to membrane formation Hyaline membrane may possibly be associated with hypersecretion of alveolar lining substance[12] which raises the question whether abnormal autonomic nervous stimulation enhances its formation, not only by promoting pulmonary œdema but also by increasing secretory activity in the terminal air-passages

Although highly specialised techniques have revealed fibrin in hyaline membrane, this does not stain for fibrin by ordinary histochemical methods It has been shown, however, that a hyaline material is formed when certain acid mucopolysaccharides react with plasma-proteins[13,14], and the possibility that a similar mechanism may operate in hyaline-membrane formation has been investigated by CARONE and SPECTOR,[15] who induced pulmonary œdema in rats by means of α-naphthyl thiourea and then introduced, by the endotracheal route, various substances including dextran sulphate, nasal mucus, meconium, and concentrated amniotic-fluid suspension. All these substances contain acid mucopolysaccharides, and all produced a membrane which had similar tinctorial properties to those of the membrane found in the human lung and which also failed to stain for fibrin. This suggests that, if hyaline membrane is indeed largely composed of fibrin, then this is probably in a polymerised form. Similar membranes were also produced when these acid mucopolysaccharides were introduced via the trachea together with plasma-protein in animals not previously given α-naphthyl thiourea.

Even if the membrane is largely composed of fibrin, the reason for the chain of events leading up to fibrin precipitation in the lungs of some infants but not of others still has to be found. A possible clue is afforded by the work of LIEBERMAN.[16] As a result of preliminary studies he postulated that a deficiency of lung plasminogen-activator activity predisposed certain infants to hyaline-membrane formation. It could be objected that such a low enzyme activity might result from exhaustion of supply by the disease process itself[17], but any such doubt has been largely settled by LIEBERMAN and KELLOGG,[18] who have now evolved an improved technique for measuring tissue plasminogen-activator activity. They describe their findings in specimens obtained from 61 fœtuses and newborn infants, comprising 15 cases of hyaline membrane and 46 controls. All but 2 (4%) of the control series showed plasminogen-activator activity, and none showed any inhibitor activity. By contrast none of the 15 membrane cases showed activity when lung cubes were examined, but in 2 out of 11 cases homogenised tissue showed some activity. The remaining 9 cases studied by tissue homogenisation showed no activator activity, and in 8 of them evidence of inhibitor activity was found. These results confirm the previous observation of defective plasminogen-activator activity in association with hyaline membrane. The inhibitor of the enzyme, found in most of the affected lungs, may explain the lack of success which has attended the therapeutic use of fibrinolytic agents in affected babies. In a preliminary communication in our present issue Dr FLEMING and his associates at the National Naval Medical Center at Bethesda report apparent absence of plasminogen activator in the lungs of two men whose hyaline membrane followed "total body irradiation", and their findings in dogs were consistent with the view that irradiation produces a potent inhibitor of activation. LIEBERMAN and KELLOGG suggest that, in infants, the enzyme defect may be genetically determined.

SETNIKAR et al.[19] suggested that an alveolar transudate is an essential part of amniotic fluid. If this is so, a rich source of fibrin is contained in the fœtal lung, and, if fibrinolytic activity is defective or absent, fibrin deposits may gradually accumulate and form into membranes after the onset of respiration. Again, deficient proteolytic activity in the lung may interfere with the alveolar lining layer and so affect the surface tension in the pulmonary air-spaces. Such an increase in the surface-tension is thought to promote atelectasis.[20]

Although much work is being done on hyaline membrane, it is abundantly clear that our understanding of its formation is still deficient, and no effective remedy is in sight.

Troubled Families

"… the State's principal duty is to assist the family in carrying out its proper functions."

So say the Ingleby Committee whose report,[21] published last week, gives important and far-reaching advice on means of helping delinquent, disturbed, and neglected children under 17. Unfortunately cause and prevention did not enter into their terms of reference, but it is clear that the committee believed that the family and the relationships therein were the primary causes of later difficulties, whatever secondary influences may subsequently play a part—an emphasis which colours the recommendations throughout. The parents, as much as the disturbed child, need to alter their ways, and the committee have wisely regarded the child as a person to do things *round* rather than the patient or sinner to do things *to*.

Set up by the Home Secretary in 1956, the committee[22] record that at that time falling delinquency-rates and fewer maintenance and affiliation orders set a scene which, if not rosy, was at least hopeful. But since then this trend has been dramatically reversed, so that the Ingleby recommendations gain much in significance and will be given prompt Governmental scrutiny.

Considering first the ways in which help reaches the family, the report notes that inter-service rivalry has, in the past, impaired coordination and delayed the arrival of appropriately trained workers. Thus, while the committee welcome the help of almost any agency in bringing troubled families and children to notice, diagnosis and treatment require tactful handling and, very often, special skills not always found among those who concern themselves with the personal affairs of others. A reorganisation of the various family services is called for, with the establishment of an independent "family bureau" responsible only to the clerk to the local authority. Detailed consideration of local-government changes was beyond the committee's terms of reference and they urge further study of this matter, bearing in mind that differing local circumstances will call for flexibility in legislation designed to ensure efficient coordination. The report declares that "… there should be a general duty laid upon local authorities to prevent or forestall the suffering of children through neglect in their homes," and such authorities should be required to submit schemes for Ministerial approval The only bodies, the report goes on, with the power to bring a case before the courts should be the police and the local authority—a move, it seems, away from the sometimes harmful multiplicity of authorities bearing on the family This proposal, which removes such power from the National Society for the Prevention of Cruelty to Children, is likely to be a contentious one when debated in Parliament and elsewhere, but it is in tune with the legitimate trend towards professionalism in social work The days of the keen but untutored amateur are passing, and rightly so The reluctance of the committee to widen "juvenile liaison schemes", run by the police for cautioned offenders, springs from similar judgment

[21] Report of the Committee on Children and Young Persons. Cmnd. 1191. H.M. Stationery Office. Pp. 179. 8s.
[22] The members were Lord INGLEBY (chairman), Lady ADRIAN, Hon. Mrs P. L. AITKEN, Mr R. H. BLUNDELL, Mr DONALD FORD, Dr R. M. JACKSON, Mrs M. M. C. KEMBALL, Mr G. H. McCONNELL, Prof ALAN MONCRIEFF, Viscountess RIDLEY, Dr P. D. SCOTT, Mr G. A. WHEATLEY, Alderman D. T. WILLIAMS, and Mr J. P. WILSON.

Turning to jurisdiction, the committee note the trend, over the past century or so, towards separate provision under the criminal law for the young and, more and more, towards emphasis on the welfare of the child as the overriding concern This has led, the committee believe, to inconsistencies The principle of criminal responsibility and punishment for a certain act in a judicial setting has become uncertainly combined, by statute, with the obligation to serve the child's best and broadest interests Thus a trivial offence may, when the full appalling family circumstances become known to the court, lead to a seemingly severe and drastic disposal Furthermore, the widening of the court's function in 1908 and 1933 permitted a child to be sent to an approved school (a severe punishment very often) for the non-criminal offences of being "beyond control" or in need of "care or protection" In rethinking the place of juvenile courts the committee concluded cautiously that, however much a child may seem likely to benefit from interference by the State, compulsory intervention should not be applied except for the clearly defined and well-known reasons that already obtain The basic pattern of courts, too, with lay justices still finds favour with they committee, though they concede some virtues to the non-judicial tribunal

The trend away from criminal jurisdiction, however, should be urged forward, notably by raising the minimum age of criminal responsibility from 8 to 12 years, and later perhaps to 13 and 14 Though an important change of principle, the practice of the law would not be as much affected by this as might be imagined Already offending children under 8 may be brought before a court and dealt with as "beyond control" the court, under these proposals, will certainly not allow children to "get off", indeed by the greater thoroughness of the procedure, Society may expect better protection than before Children under 12 would no longer be charged with an offence, though if such were established (under the usual rules of evidence) it would count towards showing that the child was "in need of protection or discipline"—the new form of words empowering the court to take action The procedure would be swifter (cases would have to be tried within 28 days of detection, save in special circumstances) and more holistic, taking in the whole circumstances of the case The police and local authority would consult before proceedings began Though retaining the power to remove a child from home, the court would do so only when it was satisfied that his needs could not be somehow met without such action, and it would have the additional options of ordering attendance at an attendance centre or study in a remand home Fines and detention in detention centres would be withdrawn, but compensation to a maximum of £100 and/or costs could be demanded Committal to the care of a "fit person" would remain, and parent or guardian could be ordered to enter recognisance to exercise proper care and guardianship The court could also order supervision by a probation officer or other person for up to 3 years From 12 to 17 years procedure would be much as it is now, and the committee did not feel that the age-limit of 17 for juvenile courts should be raised, though they wondered whether a sort of half-way "youth court" for ages 17 to 20 or 21 might be examined further

The committee believe that the court needs to be much more active with the parents, summoning the attendance of both, bringing home to them their share of responsibility, and offering support where it is practicable The verdict of the court—so often a source of grievance—would be explained to them as far as possible Treatment, where compulsory, appears as punishment, and the committee admit that in practice it is impossible to distinguish between them On the other hand, parents would no longer have the right to bring children before the court as "beyond control", though appeal to the local authority might sometimes have the same effect if no other solution could be found Here, however, parents would not appear in the role of prosecutor, and the need for them to make damaging and rejecting statements towards the child in public would be reduced

The greater part (some 400 out of 550 paragraphs) of the report is a review of administrative detail arising partly from this survey and related to courts, sentences, and corrective institutions Few of the numerous recommendations will be disputed, nor are many of wide interest, important though they are Thus, an adequate course of training is recommended for all juvenile-court magistrates, who should usually be lay people, appointed between about 30 and 40 and retiring at 65 Better court-room accommodation for the children is needed, and the report calls for removal of all legal obstacles to accelerate the disposal of cases involving child witnesses, plus closer liaison with adult courts where necessary The committee approved the attendance-centre principle sufficiently to want to lower the minimum age to 10 and to widen the categories of offenders treated there For detention centres, however, a uniform 3-month sentence should take the place of the present sliding scale between 1 month and 6 (for under 17s only), and the committee are surely right in pressing for compulsory aftercare for a further 6 or 12 months

Approved schools are left much as they are, with a few hopeful calls for inter-school staff discussions and better psychiatric facilities, staff, and aftercare. Recent months have made it clear that all is far from well among the approved schools, but from present knowledge it is hard to see how the committee could go further than they have, timid though their recommendations seem. Finally, the committee want to extend somewhat the prosecution of cruel parents (to take in mental suffering short of actual derangement) and to increase the penalties to £100 or 6 months' imprisonment or both, though at the same time full use should be made of residential training and social aid.

In sum, these proposals do not seem to conflict with any of the many other Governmental reflections of recent years, and they all have it in common that the big problem in realising them is shortage of staff and money. (We have now heard from so many committees that a "survey of reports" might help to place the future of our social services in comprehensive perspective.) There is little of dynamite in the Ingleby recommendations. Juvenile-court organisation, in particular, has been left largely alone, to the disappointment, undoubtedly, of many. But the committee have reached a quite surprising degree of unanimity after their 4-year pilgrimage, and few who advocate sweeping changes have given such careful thought to the implications. These proposals, in the present state of therapeutic knowledge, are probably as far as we should go and must carry an excellent chance of early Parliamentary acceptance. Coming when voluntary acceptance of child and family guidance services is spreading and when compulsory treatment for "psychopaths" is becoming possible under the National Health Service we have now the foundations of an excellent service for children. The wisdom of this report cannot be in doubt, and the sooner it all happens, the better it will be for everyone.

Annotations

SOCRATES IN HARLEY STREET

Some two years ago, in a week when medical education was being considered at a formal conference in London, we printed a less orthodox discussion of the same problems in our peripatetic columns. It began:

> ALCIBIADES. Tell me, Socrates, how can we be sure that our doctors are well trained?
>
> SOCRATES. Do you think it right, Alcibiades, that we should say of a pudding that it is good or bad?
>
> ALCIBIADES. Certainly, Socrates.
>
> SOCRATES. It must be possible then to distinguish a good pudding from a bad one?

This learned ballon d'essai pleased readers, author and editor. Socrates was offered a column of his own, and throughout 1959 under the heading of "Dialogues of Today" he and his disciples debated in our columns some of the social and moral uncertainties of medicine and humanity, of our time and all times. Because the dialogues deal with problems which belong not only to medicine and not only to this country, we have reprinted them as a small book (with paper covers)[1] for the consideration of all who enjoy a good argument.

The dialogues range from birth control to death control, from ways of constituting a committee to the reasons for constituting a college, from the atomic bomb to less final methods of retirement. But if the matter is serious the manner is never heavy. No dogmatic conclusions are offered and the reader is left to continue the debate with his own friends—and perhaps with himself. The anonymous author admits that he has chosen the conversational form with provocative intent. His introductory quotation, borrowed from David Hume, another writer of dialogues, describes dialogue writing as peculiarly suitable for a topic which is obvious but important or for one which is so obscure and uncertain that the human reason can reach no fixed determination with regard to it. "Reasonable men," Hume adds, "may be allowed to differ, where no one can reasonably be positive. Opposite sentiments, even without any decision, afford an agreeable amusement." We hope that all our reasonable readers will find agreeable amusement with Socrates.

CHOLESTATIC VIRAL HEPATITIS

Even before the 1939–45 war it was recognised that a varying but small proportion of cases of epidemic viral hepatitis differed from typical cases in the difficulty with which they could be distinguished from cases of extrahepatic biliary obstruction.[1] Histologically the liver in such cases was characterised by the extreme mildness of the parenchymal lesions and their restricted focal distribution, the conspicuous features were multiple intralobular plugs of bile and moderate to severe infiltration of the portal tracts with both mononuclear cells and polymorphs. Hitherto deviation from the more usual pattern of the disease has not been satisfactorily explained.

Dubin et al.,[2] on the basis of their experience at a U.S. Army Hospital in the years 1951–53, suggest that the cholestatic form of hepatitis may be due to a variant of the usual virus. Their clinical material comprised 93 cases of viral hepatitis in which biopsy of the liver was undertaken within twenty-one days of the onset of jaundice. By means of clearly defined criteria these cases were classified into four types. Type A showed the diffuse necrosis with very slight bile stasis that is typical of classical viral hepatitis. Type B was similar, but intralobular plugs of bile indicated some added cholestasis. Type C was characterised by focal distribution of the parenchymal lesions and predominance of cholestasis. In type D parenchymal necrosis was negligible, the changes consisting almost entirely in bile stasis and cellular infiltration of the portal tracts. Patients with lesions of types A or B were regarded as having classical viral hepatitis, and those with lesions of types C or D as having the cholestatic form. When the cases were classified into serum hepatitis and infective hepatitis according to whether or not the patient had received a transfusion of blood or blood product in the six months preceding the appearance of jaundice, correlations appeared between serum hepatitis and the classical picture and between infective hepatitis and the cholestatic form This, however, was contrary to the results of all previous studies, and further analysis showed that the more probable correlation was between the variety of the disease and the area where it was contracted Thus of the 36 patients with serum hepatitis, of whom only 5 belonged to the cholestatic group, 30 had been transferred with their disease from the Far East, whereas of the 54 patients with infective hepatitis, of whom 21 belonged to the cholestatic group, only 8 were from the Far East and 46 were of local origin All 21 cases of cholestatic hepatitis occurred among the 46 local cases of infective hepatitis which suggests that the local epidemic virus had a remarkable predilection for inducing the cholestatic form of the disease Since no other factors, such as exposure to drugs or toxins, were apparently responsible for this distribution of the cholestatic form, Dubin et al feel justified in attributing it to some special property of the virus The even higher incidence of this form in the epidemic in Delhi described by Smetana[3] can be taken as evidence of widespread distribution of this variant of the infective-hepatitis virus

THE GENE

IN a British Association Granada lecture delivered in London on Sept 27, Dr G W Beadle, professor of biology at the California Institute of Technology, surveyed mechanisms of heredity There seems to be no doubt that it is the cell nucleus that contains the primary hereditary message, the gene being the simplest unit of biological instruction, and some 10^4–10^6 of them being necessarily present in every human egg The only nuclear constituents of sufficient complexity to carry such a message are the proteins (linear polymers of some 20 different aminoacids) and the desoxyribonucleic acids (D N A) (linear polymers of only 4 different nucleotides) Evidence favouring D N A as the carrier arose initially from the demonstration that bacterial transforming factors (which cause a typical inherited change in some pneumococci) were composed almost entirely of D N A ,[4] but perhaps the most direct proof came from a study of a bacterial virus with inheritance characteristics known to be particulate These bacteriophages consist of a protein coat surrounding a core of D N A , and electron microscopy had suggested that the protein coat did not enter the cell during the process of infection The protein coat was therefore labelled with ^{15}N and the D N A with ^{32}P, and it was conclusively shown that only the D N A entered the cell Thus since these viruses have genes, and since only viral D N A entered, the viral genes must be D N A

The double-stranded D N A molecule,[5] where the sequence of nucleotide units in one strand automatically determines the complementary sequence of its partner, gave a clear indication of how accurate replication could occur provided that sufficient energy was available to separate the two strands by some sort of untwisting process[6] There is certainly enough D N A in a single human egg to carry all the required information, for about 10^{10} nucleotide units exist in the 46 chromosomes of the fertilised egg (ignoring the sex chromosomes), and such a number is probably sufficient to encode the contents of some 500 large books

The gene, then, can be thought of as a segment of the D N A chain, perhaps some 1000 nucleotide pairs in size, and the process whereby such a gene may direct the synthesis of an enzyme involves transferring the code to ribonucleic acid (R N A) (known to be associated with the chromosomes at certain times) by some kind of template system The nuclear R N A then passes to the cytoplasm, where it becomes incorporated into the microsomes Special segments of this R N A bind and activate specific aminoacids, which are thereby held in the correct order for the synthesis of the particular enzyme This type of synthesis probably occurs only when the enzyme substrate is present—so providing a necessary control to prevent every cell from undertaking all possible syntheses In this way differentiation may be controlled by environment A clear example of such genetic control of enzyme synthesis is the inherited condition of galactosæmia, where the patient wholly lacks the enzyme which changes galactose into a usable form

Mutations can be thought of as alterations of the sequence of nucleotides in the genic D N A either chemically (for example, nitrous acid changes D N A amino groups into hydroxyl groups and so upsets the hydrogen bonding on which accurate replication is thought to depend) or spontaneously under the influence of natural radiations Only occasionally, however, does such a mutation lead to an organism of increased reproductive fitness and so to a permanent evolutionary change

Professor Beadle ended by suggesting that paths now seem open, beginning with a universe of hydrogen, to an evolution through other elements, simple inorganic and then organic compounds, then through more complex organic systems to polynucleotides and proteins, the simple virus-like molecules, simple cellular systems, and finally to man himself

FROZEN BLOOD FOR TRANSFUSION

THE Cohn fractionator[1] is designed to separate individual half-litre units of blood into the component parts—red cells, platelets, and plasma—and to wash the red cells free from plasma It consists of a bowl centrifuge whose temperature can be kept constant, and whose bowl and associated containers can be sterilised Haynes et al have been using this machine for the long-term preservation of blood for transfusion The cells are washed with solutions containing up to 50% glycerin, then frozen at −80°C or −120°C, and after storage for 1 to 44 months thawed, deglycerinised, and reconstituted with an appropriate diluent According to requirements, the cells can be resuspended in saline, their own serum which has also been frozen, or 5% human albumin in an isotonic salt solution, to which can be added, as needed, buffers, globulin fractions, or components of clotting systems Of the red cells taken from the donor, 82% reach the recipient, and these seem to survive in his circulation as long as fresh cells Results have been so satisfactory that this frozen and reconstituted blood has been in routine use at the U S Naval Hospital in Chelsea, Mass , for more than a year So far over 1000 units have been administered without trouble, Haynes et al remark that febrile reactions have been remarkably few, and hepatitis has been absent

The cost of these benefits is considerable Rough costing suggests a figure of about £6 per unit, excluding building and heating, and a team of six workers using two fractionators can process only 200 units monthly Many London hospitals, dealing with 15,000–20,000 inpatients a year, may need over 500 units of blood in a month This would call for five fractionators and a team of twelve or fifteen, besides the existing staff of two technicians and a part-time doctor The cost of each bottle of blood for transfusion would rise from the present £1 25–1 5 to something like £6–7 Further, such hospitals use blood chiefly to treat unexpected hæmorrhage, relatively little blood is used for elective surgery or for the treatment of anæmia, so a large supply of fresh, or already reconstituted, blood would have to be kept on hand Now that the incidence of post-transfusional hepatitis has been reduced to 1 in about 800 transfusions, there seems to be little point in providing this expensive equipment for individual hospitals

On the other hand, there may be a case for setting up a few processing units for blood of unusual groups Very rare red cells such as -D-, could be reserved against need, and a moderate stock of blood of the less common groups which may be needed for extracorporeal circulations could be established In the past few months, because many regular donors have been on holiday, there has been a shortage of blood of all kinds,[3] which fortunately has led to nothing more serious than the postponement of elective operations for a week or two, it might be possible to store blood collected in the autumn, winter, and spring against the needs of the summer But such a project is bound to be expensive, and it is doubtful whether it would produce more benefits than would half the money spent on something else

SHINGLES AND CHICKENPOX

Wesselhoeft,[4] in delivering the sixteenth Charles Value Chapin oration, took the opportunity to review past and present ideas about the nature of chickenpox and shingles, and gathered into a valuable bibliography accounts of experiments and observations from many sources Those who thought that Weller and Coons [5] [6] in the laboratory, and Hope-Simpson [7] in the field, had convinced the medical profession of the unitary nature of varicella, however contracted, may be disappointed by the note of agnosticism on which he ended his address

The journals tend to give more space to rare than to common events, and this predominance may disturb the balance of a comprehensive review Rare occurrences are informative and must not be dismissed, but, still less, the common pattern of behaviour of a disease should not be overlooked There is a real danger of missing the wood for the trees, especially rare trees

The common relation between shingles and chickenpox is as follows Both can cause chickenpox in susceptible contacts, though the risk of this happening after contact with shingles is less than a third of its happening after contact with chickenpox. In either case the resultant disease is, by clinical, epidemiological, and virological criteria, ordinary chickenpox On the other hand, neither chickenpox nor shingles gives rise to an attack of shingles in contacts, whatever their previous history of either disease This is the usual pattern shorn of rare exceptions, and it determines the epidemiological behaviour found in practice—namely, that chickenpox appears in epidemics when aggregations of susceptible persons are effectively exposed to cases of chickenpox or shingles, but that shingles does not itself appear in epidemics and is independent of epidemics of chickenpox

For the " dualist " who holds that there is a distinction between ordinary and zoster-induced varicella there is a difficulty that seems never to have been adequately considered How far backwards must the antecedents of a case of chickenpox be traced before it can with certainty be classified as " ordinary " and not " zoster-induced "? Are ten generations of ancestry to be considered adequate evidence, or a hundred or a thousand? One observer traced back an outbreak for twelve months and classed it as " ordinary varicella " Had he, by pushing the inquiry still further into the past, found that the outbreak in fact stemmed from an original case of shingles, he would have been compelled to reclassify it as one of " zoster-induced varicella " Except in remote areas it is seldom possible to back-track in this way with any certitude, and, in such remote regions, outbreaks are commonly found to stem either from a local case of shingles or from a case of chickenpox imported from more crowded areas where further investigation of the lineage of the virus is difficult On all the evidence, it should surely be conceded that there is only one chickenpox, which can be caught either from another case of chickenpox or from a case of shingles

Much remains to be understood, foremost the nature of shingles itself If, as seems likely, it is due to the reactivation of latent chickenpox virus, where in the body is the latent remnant? Do all who have had chickenpox depend upon the survival of this latent brood for the preservation of their immunity? How is the symbiosis disturbed so that a harmony of maybe fifty years breaks down, the eruption develops in a dermatome, and infectious chickenpox virus escapes into the environment? On questions such as these light may be shed by the more unusual happenings, the anomalies and exceptions to the common pattern described above The least uncommon anomaly is the occurrence, usually in children, of a zoster during a primary attack of chickenpox—an apparent exception to the rule that contact with chickenpox does not give rise to shingles Much rarer are those cases in which shingles in an adult appears to have been caused by contact with another case of shingles or a case of chickenpox. How uncommon this is was shown by a prospective study of thousands of contacts of cases of chickenpox and shingles of whom not one developed shingles Nevertheless cases have occasionally been recorded in circumstances that make them very unlikely to be fortuitous Again there are a few records of attacks of zoster-induced varicella failing to protect against subsequent exposure to chickenpox All such rarities must find their explanation in a more complete understanding of the two diseases, but in the meantime they should not be allowed to obscure the picture which is already emerging

Even if some laboratory refinement should in the future discover a recognisable peculiarity of virus newly released by an attack of shingles from its intracellular confinement, the interesting observation would no more disturb the ætiological picture than a similar finding in spirochætes from late cases of syphilis would unsettle our present conception of that disease

The Wider World

MEDICINE AND THE NEW AFRICA *

The Passing of Colonialism South of the Sahara

H S GEAR
M D, B Sc W'srand, D P H, D T M & H
FORMERLY CHAIRMAN, EXECUTIVE BOARD, WORLD HEALTH ORGANISATION, DEPUTY CHIEF HEALTH OFFICER, UNION OF SOUTH AFRICA

Africa south of the Sahara forms a unit of countries with many common features Because of early remoteness, climate, and disease, it was until lately isolated from Europe, and so lacks written history Its peoples—Bantu, Negro, Hamite—have many common physical and social characteristics It is the Africa of the tropics and semi-tropics, with desert, jungle, heat, and sun obtrusive - It has been the region of the world most affected by European colonialism It has had an evil name because of the men, especially those coming from temperate lands, who have been killed or disabled by its sicknesses

European influences were first brought to the continent by explorers, missionaries, traders, and prospectors In the 19th century the Colonial Powers, scrambling after them, launched tribal Africa into the Western way of life, and brought it precipitately into the material and technological world created by the Industrial Revolution Through the colonial agents of this world phenomenon, Africa was in time largely freed from the blight of tribal massacres, slavery, starvation, and epidemic disease

Today Africa is impatiently grasping the outward forms of sovereignty More than half her peoples will achieve political independence this year, and before the decade is well advanced the rest will almost certainly have followed Colonialism will then have vanished and new, and largely inexperienced, States will be struggling with the daunting social problems of emerging millions This fact, partly political though it may be, directly affects the future of medicine in Africa

The astonishing reduction in the amount of disease during the past 60 years has been possible because colonialism gave Africa a phase of social stability with a rising economy, and the whole paraphernalia of good central and local civil administration Western medicine had then its opportunity to prevent and cure disease " en masse "

Western ideas have moulded the form medicine has taken both in sovereign countries like the Union of South Africa and the Federation of Rhodesia and Nyasaland, as well as in the Colonial territories of Belgium, France, Portugal, and the United Kingdom In this medicine there has been a significant place for the medical missionary, the private practitioner, the medical professional association, the autonomous university with its medical school, and the public but unofficial research institution It has been a medical system constantly nourished and refreshed from the European home countries

But, though this European form of medicine has given a place to the non-governmental and the non-official, most medicine in Africa has a strong official character The hospital and clinic services of South Africa and the Federation and the general Colonial Services, despite their Western origin, are largely official and depend on Government funds for providing free or subsidised services

If the future held no other obstacles, the official nature of most of the developing African medical systems would create difficulties enough This official bias will be continued by most forms of external aid It makes uneasy those who would like to see the individual doctor and the non-official organisation claim a worthy place

Medicine, in a full sense, today only achieves results if there is an adequate community with law and order, efficient civil administration, good communications, and a sound economy In other words the good health of a community needs not only good doctors, but also well-run cities, villages, and country districts with sufficient food, pure water, efficient waste-disposal, proper housing, and all the other advantages of good government Inevitably the changing political and social scene in Africa will alter the future of medical and other public services

UNITED NATIONS AID

The New Africa is being moulded by external as well as internal forces The most important stimulus comes from the United Nations family, with the World Health Organisation as the agent responsible for health and medicine It is perhaps not fully realised how great a change is being wrought by the United Nations agencies, even though they are intergovernmental and not super-governmental organisations

Delegates from African States appear in ever-growing numbers in the councils of the world and many already have been effective office-bearers African regional and other offices already represent the U N Economic Commission for Africa, the U N Technical Assistance Administration, the Food and Agriculture Organisation, the World Health Organisation, and the U N Children's Fund Most of these directly or indirectly affect health programmes, and as a group are not insignificant in power and resources

A stream of people—consultants, technical experts, advisers, and others—are being directed by the U N group into Africa Another stream flows out carrying delegates, committee representatives, and postgraduate fellows and students

People moving in and out of Africa as part of its technical and scientific evolution are not a novelty But there is something very different about the flow sponsored by the United Nations family The volume is more impressive and it is directed to and from many more countries U N consultants and technical experts now working in Africa come not only from the United Kingdom, France, and the other colonial countries, but from North and South America, the whole of Europe, and several Asian countries The Africans travelling overseas for experience and training also visit a much wider range of countries

The technical aid in medical fields is massive It is gladly accepted by the new African States without the undue sensitivity they sometimes show to aid offered by individual foreign Governments As a result, the organisation of hospital services and clinics, and the training of doctors, nurses, and other staffs have been speeded up

A fundamental principle in this form of external technical aid is to be noted Since the United Nations system is official and intergovernmental, it works through national governmental services It is thus a force which quite properly creates and strengthens official and governmental services in the countries it helps It is supporting officialdom everywhere, and will increasingly do so in the future African medical and other services This is satisfactory provided non-governmental organisations and arrangements are not neglected

---

* Based on a lecture delivered under the auspices of the Institute for the Study of Man in Africa, Johannesburg, on June 14, 1960

OTHER INTERGOVERNMENTAL ARRANGEMENTS

The passing of direct colonial control and the arrival of United Nations technical aid do not mean that the Colonial Powers have given up all responsibility for emerging Africa They are helping in the development of such things as general administrative services, universities, hospitals, rural clinics, research institutions, water-supplies, and roads Their hope is that if the new countries have sound public services the transfer of authority to peoples who, though politically active, are on the whole administratively and technically inexperienced will be smoother

It is not only the old Colonial countries which are eager to help the New Africa The Union of South Africa has often and officially stated that it wishes to draw on its own rich technical resources to help the rest of Africa Such help has already been given in many ways

Several South African scientists have visited other African countries, some have served as consultants, a few students from other territories have been trained in the Witwatersrand, Cape Town, and Durban Universities and medical schools, some research teams have worked on general African problems, and the South African Institute for Medical Research is used by many medical services as far away as the Sahara It is also part of several international scientific networks—e g , in virus diseases, spirochætal infections, bilharziasis, malaria, and so on

However, it is doubtful if South Africa yet plays a part proportionate to her technical resources Compared with the many scientists and doctors working in the New Africa who have come from Britain, France, and other European countries, or with the hundreds of undergraduate and postgraduate African students who flock to other medical centres, South Africa seems inactive Yet unless she vigorously develops this two-way exchange of medical scientists and students, her own medicine and science may languish as an international or African force

A more recent feature of intergovernmental technical aid to Africa is the bilateral governmental system Its first great advocate was the United States of America, and Africa has benefited liberally American medical missions are important now in many African states, and there is a steady stream of African students to the great medical and public-health schools of the United States She is keen, too, to cooperate with local groups in research into the many tropical and other diseases which are still difficult to control or treat such as bilharziasis, malnutrition, and many parasitic conditions

But the American bilateral programmes are having some unexpected imitators The Communist countries are already at work in many fields, including medicine, and it is probable that the Chinese will also join in sending technical experts and attracting fellows and students from the African States

NON-GOVERNMENTAL INFLUENCES

The pioneers of Western medicine in Africa, as elsewhere, were not officials but private doctors, and the medical missionary was the pioneer of the pioneers For a hundred years these courageous and selfless people have been among the great medical and social liberators of Africa Their work, generous and independent, goes on Today it is perhaps again critical If tolerated in the new countries, these societies could be a valuable instrument in continuing the spirit and practice of personal and non-official medicine of the best type

It was earlier inevitable, in tropical and tribal Africa, for the Colonial Powers to break the shackles of epidemic and endemic disease by introducing modern medicine through official services So, with the important exceptions of the larger European communities, the private doctor has not been a force

Again, with the exception of South Africa and Southern Rhodesia, medical and nursing professional associations have had an insignificant influence on medical and health policies in Africa compared with the part they have played in Europe and America The professions are generally a sound influence on official ministries, for in considering national health problems they usually hold more than a narrow professional view They contribute wisdom and experience and usually add to the maturity of the community It is, therefore, unfortunate that strong professional associations with a backbone of independent doctors seem unlikely to develop in the newer African States

Yet, paradoxically, one of the dangers threatening medicine in Africa is the private doctor who abandons the ethical code of his profession The charlatan in Africa is already playing on the credulity of the naive and superstitious He may be witch-doctor, masquerading doctor, or qualified practitioner prostituting his calling The new States, therefore, have a clear responsibility to protect their people from exploitation But the State will not succeed in this aim without a medical profession of the highest integrity keen to keep its own house in order

Industry has also contributed to African medicine Most large industrial organisations have acknowledged their obligation to protect the health of their communities In the gold, copper, and trading industries of South Africa, the Rhodesias, the Congo, and West Africa hundreds of thousands of workers are given health and good physique and learn much about keeping themselves fit during the years of their employment Much of this knowledge diffuses into the kraals and villages Hence the position of industry in the new States is of concern to medicine If they accept that private industry can contribute to the economy, this will open a useful opportunity for non-governmental medicine

Another non-governmental agent which could do immeasurable good for medicine in the New Africa is the large philanthropic or public Foundation In Africa the Rockefeller and other American foundations have been joined by the Nuffield Foundation, whose support for the establishment of a vigorous and modern medical school in Salisbury is likely to be one of the germinal events in Central African medicine As Africa changes from colonialism, the great Foundations, both American and British, will have an opportunity of service greater than in the past They are altruistic, objective, generous, and free of politics and bureaucracy They thus can balance the help coming to Africa from the intergovernmental agencies—multilateral or bilateral—with the best type of non-governmental support It will be unfortunate if the new States are unwilling to invite the Foundations to help in the large new medical, technical, and social programmes for which they will soon be responsible

A final example of non-governmental health and medicine is the voluntary organisation In South Africa and the Rhodesias, and to a lesser extent in the Colonial Territories, such bodies have been valuable, and it is to be hoped that the New Africa will encourage the work of voluntary groups, particularly in child and maternal health, first-aid, accident prevention, and social welfare But many circumstances are against them, especially if the new States loosen their Western relationships

SOCIAL TRANSFORMATION

The New Africa to which medicine must adjust itself is as much a product of social, including economic change as of the more obvious political movements These social changes—in such things as education, economy, agriculture, industry, science, and communications, and in religion—have been accelerated by the results of Western medicine The reduction of pestilence, as much as the control of famine and tribal warfare and the abolition of slavery, launched the African social revolution Now, along with the present political and nationalistic movements, these social forces are influencing the future setting for African health and medicine Indeed the replacement of the social customs of tribal Africa, by something modelled on, or influenced by, external ideas and examples, is happening too rapidly for medicine and the other social services to keep pace Even if these social forces are not diverted or delayed by political troubles, medicine in the New Africa will still have to face problems very different from the old

One is already ominous—the growth of population Released from the old checks of slavery, starvation, tribal war, and preventable disease, the annual rate of increase in some territories is already 3% People are migrating into the towns and factories, and large urban and industrial populations may place an unbearable demand on public, including medical, services The witch-doctor is no longer supreme Old fears have gone, so that hospitals and clinics are being swamped, and overworked doctors and nurses are driven to exhaustion Africa, like most other developing countries, has too many ugly and squalid towns and villages, and yet their inhabitants increase relentlessly to make slums more depressing and dangerous Only watchful sanitary administration and good fortune seem to explain the relative absence hitherto of serious disease

Another feature of the social transformation of importance to the medical reformer is the growing emancipation of the African women In much of Bantu society women still lack freedom and are only slowly training as midwives, nurses, health visitors, or teachers Sufficiently educated girls are deplorably few to meet the urgent demands of nursing and teaching

CHANGING PATTERN OF DISEASE AND DISABILITY

Africa's reputation has not yet recovered from the casualties among those who in earlier days came to explore, trade, or fight Portuguese missions defeated by fever, Mungo Park's expedition ending in disaster, Dutch, Danish, French, and British trading-posts on the West and East coasts enlarging their cemeteries daily, the decimation by typhoid and dysentery of the South African, and by the malaria and dysentery of the East African campaigns of the first world war—these and many more gave a sinister name to the climate and disease of Africa

Before medical science unravelled the maze of tropical disease, the hazards of Africa seemed to lie in its malignant climate Sun, swamp, heat, miasma—all were accused However, recognition of the true situation has seen the dramatic conquest of most of Africa's pestilential and tropical diseases Not only is the indigenous African population doubling itself every 30–40 years, but European families are living happily and healthily even in such dreaded areas as the West Coast and the Central African Valleys If one of the 18th or 19th-century Europeans returned, he would perhaps be chiefly amazed by the contempt of the moderns for the huge pith helmet, red spinal pad, and abdominal or cholera belt which he considered an essential protection against the baleful African sun and climate

Today we have gone a long way towards separating the climatic and environmental from the communicable and nutritional factors in the cause of African disease The greatest triumphs were the discovery of the causes and methods of treatment and control of the tropical fevers The devastating epidemic and endemic diseases of previous centuries are now cowed Yellow fever, malaria, sleeping-sickness, smallpox, dengue, yaws, and many more are shadows of their former selves The blame placed on tropical and African climate is now known to have been much exaggerated Now we know that an efficient sanitary system and a good diet can make nearly all Africa tolerable and healthy

Formerly nearly all the dangers to life lay in communicable disease carried by insects or infected food or water Climate was indirectly responsible in that it gave these diseases the medium for their propagation With disease reduced or eliminated, tropical climates become themselves less fearsome, if still uncomfortable Today we know much about the direct effects of sunlight, heat, and humidity Unpleasant though extremes of these may be, their effects can be borne more tolerably by applying the present knowledge of the human body's capacity for acclimatisation and adjustment Much of this work was shown on the Witwatersrand—e g , the regime of adjustment to work, environment, heat, and humidity applied in the mines The human power of physiological adaptation, combined with modern housing and work places, and, if necessary, air-conditioning, is radically changing the medical view of the future capacity of Africa to support healthy human populations even in its more fearsome desert and jungle regions

With the astonishing decline of the pestilences a new pattern of diseases is appearing Some of these diseases have always existed but were overshadowed Others seem to be truly new, or much more virulent Others are a product of social change

Examples of diseases now more prominent by contrast are malnutrition and some of the dysenteries Mass famine is now rarely seen, but protein malnutrition has lately been recognised as widespread Infantile diarrhœa persists as a serious public-health hazard

A group of diseases partly old and previous unrecognised, and perhaps partly new or more virulent, is those caused by viruses Besides such well-known viruses as those of poliomyelitis, influenza, and trachoma, a whole host of new agents has been found in Africa Much of this research has been done in the South African Poliomyelitis Foundation supported by a team from the Rockefeller Foundation

Two examples of conditions aggravated by the stresses in a society shifting from the pastoral to the modern are tuberculosis and industrial disease Unfortunately tuberculosis is increasing in nearly all African territories, especially in the town and labouring groups The story of industrial expansion in other continents is unhappily repeated Again, increasingly as the New Africa becomes industrialised, the problems of disease in mines and factories will arise, especially if the vigilance of the national health and labour administrations slackens

Modern life is not only putting people into factories and towns, it is altering the agricultural scene More and more large-scale agriculture in Africa is dependent upon irrigation This is spreading bilharziasis and making the control of its snail vector more difficult Several other parasitic worm diseases and intestinal infections continue to cause much sickness and inefficiency throughout tropical areas Their reduction must await improved sanitary services and higher personal standards of cleanliness

In the new pattern of disease one feature is becoming more and more striking—accidents. Even in remote regions of Africa accidental injuries are serious. Every new road brings an almost incredible number of car and lorry fatalities and cripplings. In New Africa, as in the rest of the world, the accident of the home, road, and factory is killing and maiming people and filling hospitals in ever larger numbers.

As the acute diseases recede and as the chance of living longer in a modern world increases, the so-called chronic degenerative conditions obtrude themselves. Here, too, Africa shows signs of copying the world design. Whatever may be the full story of their causes and associations the melancholy record in more and more countries is of death and disability from heart and kidney disease, nerve degenerations, and malignant disease. The mental afflictions, too, will probably be more obvious in the future Africa.

WHAT PATTERN FOR MEDICINE?

The speed and confusion of events are unfavourable to prophecy, but once the transition to sovereignty is achieved and a new African political condition is created, what will be the philosophy and form of its medicine?

In an immediate technical sense there will be enormous tasks to shoulder. The prospects of rewarding careers will lie before the new African doctors and nurses—suffering to be relieved, premature mortality to be challenged, fuller and healthier lives to be sought for the growing millions. They will also have an enviable opportunity to probe many remaining mysteries in disease. They will be the privileged observers of the whole gigantic phenomenon of a people being changed by social pressure to accept new ways of life. Such tantalising questions as the effects of climate and environment on energy, mental capacity, physiological efficiency will be theirs to study. Medicine in the New Africa will be rich in obligation and in opportunity for research.

Public-health and preventive medical measures to meet the challenge will only be effective, indeed possible, if the general administration is competent. But even assuming that no disastrous weakness appears in the public-health organisations of the New Africa, its future medical philosophy is still uncertain.

Medicine at its best is something finer than an exercise of technical skill. In the medicine being introduced into Africa and other developing regions this broader duty is too often neglected. Yet here the need is more desperate than in the older lands where all upbringing supports understanding of such social responsibilities. The culture and civilisation which have produced modern medicine, and of which it can be a noble component, are also essential in the new countries if they are to gain completely. Medicine's true teachers and disciples give more to Africa than medical care in a hospital or clinic. Their integrity and philosophy are a demonstration of the goodness to be found in their culture. This is necessary if the struggling new African medicine is to be something more than a mere materialistic technique or rival to tribal witchcraft, which could easily revive under a cloak of African nationalism.

Western medicine in helping Africa should not overlook the need for this broader interpretation of its possible service. It should guide Africa to create people who are good doctors and nurses, but are also prepared to follow fearlessly the principles founded over many difficult generations in Europe and America. This responsibility will be more onerous in New Africa than in the older settled communities of Europe and America. But the future African doctor, by being a man of integrity and principle, will increase the stability of his country and the respect it will earn in the world.

Special Articles

THE MINISTER ON THE HEALTH SERVICE

MR ENOCH POWELL, Minister of Health, reviewed the structure of the National Health Service in an address to a joint meeting of the English and Welsh Executive Councils Associations at Llandudno on Oct. 27. He said:

"The National Health Service, by its very nature as a comprehensive State service, holds out dangers and possibilities of harm as well as opportunities and possibilities for good. We can never wholly eliminate the risks and be left with only the opportunities. What we have to do is to discern as clearly as possible where those risks lurk and what they are. We shall then be in the best position to counteract and minimise them."

The service was the channel through which flowed the overwhelmingly large proportion of our national income which we devoted to the care of health and the treatment of the sick. The fraction so devoted had not, on average, been much larger during the last decade than it was twenty years earlier—though, of course, the national income itself had been larger and so, consequently, had been the absolute amount of resources devoted to medical care. One thing was certain: as our national income continued to rise, the volume of effort and resources devoted to health would rise. Another thing, too, was certain—that with the inevitable changes in the texture of society and in the content of medical knowledge and theory, the nature of the resources and the application of the effort devoted to health would also alter. In any given state of society and medical knowledge there was an ideal application of the available resources which would yield the greatest harvest in terms of health, wellbeing, comfort, reassurance—in short, of happiness. We should never quite attain this ideal, but we ought always to be tending towards it, and success or failure in doing so depended on the nature and the functioning of the channels through which the available resources flowed. Mr Powell continued:

"It is in this context that a comprehensive State service has its dangers. In such a service responsibility is inevitably centralised—in the Minister answerable in Parliament. Because responsibility is centralised, so, in large measure, must be decision, since responsibility implies the power to take the decisions for which one is answerable. This in turn implies an administrative machine which will link all the parts together and secure conformity with the central policy and decisions. Now, all this brings with it a great danger—that of rigidity. Policies which are formed centrally and executed administratively are bound to be slower to change and less adaptable to alterations of circumstance and demand than if responsibility were diffused and decisions were independent. The great machine is bound to have a one-track mind, to be cumbrous and unresponsive, to abhor variations, to be insensitive to the world around it.

"These disadvantages apply anywhere, but in the field of health and medical care they can be specially dangerous. Here is a field in which it is the individual mind, the local experiment, even the chance observation, which bring about the great advances. The man or woman who is (as we say) before his time, at whom officialdom is bound to look askance, whom contemporaries treat as an oddity or a nuisance, turns out to be the pioneer, doing the work which determines the direction of future development These people need an environment in which they have opportunity, even encouragement, certainly not repression But how is the machine to know them when it sees them?”

Not only the methods of giving medical care, but the character of the need for it were constantly changing Post-war legislation and planning for all the welfare services reflected the conditions of the pre-war world for it had nothing else to go on They were trying now to assess the revolution of the 1950s, but it might be far into the 1970s before they could adjust the machinery to take account of it This conflict between the characteristics of a comprehensive State service and the facts of social change and medical progress could never be fully resolved, for it was inherent But by recognising it, there was much they could do to limit and counteract its dangers

Those who framed and hammered out the National Health Service were not unconscious of the dangers, and they deliberately embodied in its structure elements of independence, both lay and professional, to be a counterpoise The contractual status of the general practitioners, dentists, and opticians, the separate representation of the doctors and other professions in the structure of the hospital and executive council services, the power and authority of the professional colleges and associations—these might seem to have a fine old English illogicality in a State service “But a wise Minister of Health will see in them not hindrances but safeguards to the soundness of his work, and in all that I do or seek to do I shall be as jealous of the independence of the professions as they are themselves,” said Mr Powell

But all these built-in counterpoises in the structure of the National Health Service to the dangers of the great machine would not be sufficient if the great machine itself were all “The National Health Service is intended to be comprehensive, it is not in my view intended to be exclusive,” went on Mr Powell “For the service’s own sake, I attach the highest value to the fact that medical service and care is also available outside it and that completely independent organisations exist in the field, to support and conduct research, to study and criticise, to supplement, assist, and (why not?) overlap the services provided by authority of Parliament” He welcomed the flexibility and spontaneity which these other channels bring to the nation’s provision for health

Mr Powell recognised three trends in the modern approach to health and medical care (1) the growth of community care and aftercare of the sick, “which takes off the hospitals work which can be done more effectively and more beneficially outside them”, (2) the development of preventive and remedial measures which will prevent admission to hospital or lengthy treatment there, and (3) the more intensive and efficient use of hospital accommodation, expressing itself in higher turnover of patients and lower ratio of beds to population In two of these three the initiative in development lay with the local authorities, and if the new trends were to find full expression, the biggest expansion within the health service in the next decade would have to come on the side of local government One should note finally that as the link between the three trends is, from one point of view, the patient as an individual human being, so the link from another point of view is the friend and adviser of the patient as an individual human being—namely, the general practitioner

Turning to finance, Mr Powell declared that the financial structure of the National Health Service could not have been devised more effectually if the object had been to put the three main elements into watertight, non-communicating compartments There were in fact three separate financial systems, and consequently the interrelation between developments and decisions in each of the three fields was virtually impossible to express in the clear financial terms which would so much help administration and public understanding “However, I must say bluntly that a major reform in the financial structure of the National Health Service is farther off at present than the eye of a politician can see We must work with the structure we have got, and I shall not be content until I can see a long-term picture in which the development of the hospital service is dovetailed with the development of the local-authority services, and the future function of the family practitioner is related to both”

Dialogues of Today

SOCRATES, THIS IS YOUR LIFE!

Haemon Come in, Socrates, and don’t be surprised to see so many people We know that you are becoming an author yourself for the first time, so we thought we would like to congratulate you Socrates, this is your life!

Socrates It is true, Haemon, that I am no longer to be dependent upon Plato and Xenophon for an account of my words, but I am no author any ideas to be found in my conversations are contributed by those with whom I talk I am only a midwife, delivering other people of their ideas

Haemon Come in, Apollodorus, and tell us how you first met Socrates

Socrates Welcome Apollodorus! What have you been doing today?

Apollodorus I have been in court arguing as to whether or not certain words are obscene

Socrates Is there any more important question?

Apollodorus I should hardly have called it important, Socrates

Socrates But tell me, is not obscenity sometimes a kind of swearing?

Apollodorus Sometimes it is

Socrates And when men swear do they not use words, which are held sacred, in a way which is considered blasphemous?

Apollodorus Certainly

Socrates It would seem then that if we are to decide why words are obscene we must also consider what makes words sacred, and we can hardly do that without asking what is sacred, and why it is so So you see why I said that the nature of obscenity is a most important question But, tell me, is there any characteristic of the obscene words themselves which distinguishes them from other words?

Apollodorus I don’t know of any

Socrates Are they not all short words, usually of one syllable?

Apollodorus I suppose that is true, but surely it is not the form of the word but the meaning which renders it obscene

Socrates Surely not, Apollodorus, for if instead of a word of four letters you use an equivalent one of four syllables, the feelings of your hearer will be quite different, although the meaning is the same Does it not seem to you that a short word contains all its energy in a small space and at high tension, and at once conveys to us a physical reality, whereas a word of four syllables carries its energy at low tension, and so conveys a meaning which is emotionally diluted, and makes far less impression on the feelings ?

HAEMON Thank you Apollodorus! Now here is Analyticus

SOCRATES It is appropriate that you should have come just now Analyticus, when we are talking about obscenity, for are there not many people who think all your writings obscene, even though you use many words of more than four syllables ?

ANALYTICUS Yes, indeed, Socrates, but when I am called a corrupter of youth I console myself with the fact that they call you the same.

SOCRATES Tell us why you think some words are obscene.

ANALYTICUS I think the form of the word is only one factor, important though it is A word may transmit emotion forcibly, but the emotion is related to the thing signified If some things were not sacred swearing would lose its point, but so it would if it were not considered reprehensible, and it is reprehensible only because some things are sacred. People sometimes speak of obscenity as animalism, but that is just what it is not Animals alone are innocent of obscenity Obscenity implies a sense of guilt. If you never swear you are either perfectly balanced or too conscious of your own guilt

HAEMON Here is Eryximachus

SOCRATES Welcome, Eryximachus, for there is no one more fitted than you to explain to us the nature of obscenity, since no one behaves more shamelessly than you.

ERYXIMACHUS How is that, Socrates ?

SOCRATES Do you not discuss with your patients matters which they would be ashamed to talk about with anyone but a doctor, and when you examine them do you not insist that they should conceal nothing which their modesty makes them conceal from others ? And in all this do either you or your patients feel any shame ?

ERYXIMACHUS But there is nothing obscene in all that, Socrates, for modesty is a matter of convention and shame does not arise in the relation between doctor and patient

SOCRATES It is the same with me, for I am not only a midwife who delivers men of their ideas, I am also a physician who seeks to examine their thoughts in all their nakedness and a surgeon who practises the orthopædics of the mind And it is my aim to examine men's words and to persuade them to let them be examined in the same spirit of truth with which Eryximachus examines their bodies

HAEMON I am sure we all wish your book the success it deserves Socrates, master of words, this is

XANTHIPPE (*marching firmly into the room*) your wife! I'll give you words! Was there ever such a man ? He hasn't slept for two nights, yet here he is talking about words And he drinks twice as much as anyone else without getting drunk, and sleeps out of doors wherever he finds himself, without even a blanket. But what does any of you care so long as you can get him to discuss philosophy ? I'll give you a bit of philosophy Where do his words come from ? Where does his life come from ? Ultimately from my kitchen Think that one out, all of you! Come on, Socrates, we're going home

(*They go*)

The Widdicombe File

LXVI.—THE DIVISION OF PATHOLOGISTS

DEAR PETER,

I thought your letter* was a very sound and moderate statement of the case—as stated by a supporter of a Faculty with the Physicians Of course you were trying to be impartial, just as every decent pathologist tries to be when he rehearses the arguments, but it is just impossible. The only man who can be truly impartial is the man who does not care one way or the other, and he will not trouble to rehearse the arguments at all That presidential address which you rightly describe as statesmanlike was, I know, meant to be impartial, but to me the final section seems to emphasise the advantages of a Faculty and the disadvantages of a College

You have recited some of the arguments for and against both sides, and I would like to review some of them as a supporter of the College You quote the argument that the establishment of a College "would be a cripplingly expensive undertaking", but this is obviously untrue unless we develop delusions of grandeur and try to obtain in a few years the sort of accommodation which other colleges have taken centuries to build up The independent Faculty of Radiologists, which is doing for radiology what a College would be trying to do for pathology in its early years, is able to exist simply and economically, and so could we You quote the argument that any examination set up by the College would take many years to achieve recognition, but what is the evidence to support this view ? There is after all no really satisfactory examination at present for would-be consultant clinical pathologists, and if a College of Pathologists provides a good one I can see no reason why it should not quickly become accepted

As for the College of Physicians, it is difficult to consider it as anything but what the name implies, even though I agree that it is not exclusive, and accept that out of every 100 "active Fellows" there are about 11 administrators, 9 pathologists, 6 academic pharmacologists, physiologists, or research-workers, 2 radiologists, and an obstetrician It could, of course, cease to be primarily a physician's college, but is that the wish of most physicians ? I would agree that most clinical pathologists, if they had taken up any other specialty, would probably have wished to become physicians rather than surgeons or obstetricians But clinical pathologists are still not physicians except in so far as a few hæmatologists have their own patients, and although we certainly must remain *clinical* I see no reason why we should enter into closer relations with the physicians than with any other special group of doctors

"If we were all certain that we could trust the Physicians", you say, "I think few would hesitate to accept their offer" I think you miss the point This is not a matter of trust, but a matter of intelligent anticipation of the possibility that the interests of physicians may not always coincide with those of pathologists If they do, well and good, but suppose they do not ? You say that "if, after an honest trial we found ourselves unable to agree with them, nothing could stop the faculty then splitting off" I think you overlook the fact that the Faculty would be a creation of the College of Physicians, not of pathologists, and it could hardly split off as a body unless the parent college chose to abolish the Faculty Are you prepared to envisage a future situation when a body of dissatisfied pathologists has to try to set up an independent college in opposition to an established faculty? Then indeed the "dissensions and bankruptcy" of which you warn us might well become a reality

---

* We printed this letter from the File on Oct 22.—ED L

Our seniors often tell us that there is no advantage to them from either course, and that they are only concerned to provide for the younger pathologists in whose hands the future lies At the same time they tend, perhaps, to ignore the experience of most of those who discuss such matters with these younger pathologists, and find that they are mostly in favour of a College The young men do not seem to be afraid of starting in a small way provided that they can feel genuinely independent and not a sort of appendage to another college Their "image" of pathology is of a subject which is of real importance in its own right and which can therefore expect its own separate and individual organisation

If we are to build surely for the future, independence is the only safe choice When I have reached retiring age, I do not want my juniors to be able to say to me "You and your colleagues made a fine mess of things in 1960 Here we are stuck in the College of Physicians where we are not really happy, but it will be very difficult to break away now If you had only made the effort to form a College it would be well established by now Did you *have* to choose the easy way? Couldn't you see just a little way in front of your noses?"

Yours,

G G

Symposium

TICK-BORNE ENCEPHALITIS VIRUSES

FROM A CORRESPONDENT

The Institute of Virology of the Czechoslovak Academy of Sciences acted as hosts to virologists from eleven different countries during a four-day symposium last month on the biology of viruses of the tick-borne encephalitis complex The meetings were held in delightful surroundings at the House of Scientists at Smolenice, near Bratislava Representatives from almost all the major groups working on this subject were present, and the symposium provided an unusual opportunity for workers from many different disciplines to pool information and exchange ideas in a common approach In Britain, human infections with louping-ill virus do not present a serious public-health problem, but in Central Europe, Scandinavia, U S S R, and India viruses of the tick-borne encephalitis group are a serious menace The recent recognition of human infections with viruses of this group in Canada[1,2] and the U S A[3] extends the area in which these viruses are known

Dr J Casals (New York) showed how the tick-borne viruses were placed with yellow fever and some twenty other arthropod-borne viruses into the serological group B on the basis of antigenic relationships In the past, the tick-borne encephalitis viruses have been considered a homogeneous group in spite of wide differences in the disease patterns they produced in different parts of the world Dr D H Clarke (New York) showed that they could be divided into six antigenic subgroups on the basis of hæmagglutination inhibition tests with absorbed sera and by agar-gel precipitin tests The six subgroups were represented by the classical far-eastern Russian spring-summer encephalitis (R S S E), louping ill, Omsk hæmorrhagic fever, Kyasanur Forest disease,[4] Malayan tick-borne Langat virus, and Central European tick-borne encephalitis which included Czechoslovakian, Austrian, Finnish, Polish, Swedish, and Yugoslavian strains, as well as strains from European U S S R The recently described North American Powassan virus had not yet been examined by these techniques These antigenic differences were important because they explained the reported failure of R S S E vaccine to protect humans (Dr P N Bhatt, Poona) or mice (Dr L Daneš, Prague) against infection with the virus of Kyasanur Forest disease

As in other branches of virology, tissue-culture techniques were gradually replacing older methods for the titration of viruses and for the detection of neutralising antibodies The use of a plaque technique for the titration of tick-borne encephalitis viruses was described by Dr J S Porterfield (London) and was applied by Dr V Mayer, Dr J Zavadá, and Dr R Škoda (Bratislava) to Central European strains Dr Bhatt reported that chick fibroblast cultures were as satisfactory as mice for the primary isolation of Kyasanur Forest disease virus Czechoslovak workers preferred a two-stage process—primary isolation in tissue-culture cells which were later shown to be infected by virtue of their resistance to a challenge virus Neutralising antibodies were detected by a metabolic inhibition test carried out in Hela cells (Dr H Líbiková and Dr J Vilček, Bratislava), by plaque inhibition (Dr J S Porterfield, London), or by the direct inhibition of cytopathic effect in Hela cells (Dr E Molnar, Budapest) or in pig kidney cells (Dr D Málková, Dr Z Marhoul, Dr V Fraňková, and Dr V Černy, Prague)

Vaccines derived from formalinised mouse brain had been used for many years in the U S S R (Prof E N Levkovich, Moscow, Prof A A Smorodinstev, and Dr V I Ilyenko, Leningrad) and formalin-inactivated louping-ill vaccine had been used to protect laboratory personnel (Dr D G ff Edward, Beckenham) and domestic animals (Dr D Blascovic and others, Bratislava) Attempts at producing a vaccine from virus grown in tissue culture were reported from Prague (Dr R Benda and Dr Danes), from Budapest (Dr E Molnar), and from the U S S R The major difficulty was to guarantee complete destruction of infectivity without at the same time reducing the antigenicity of the vaccine There were many parallels with the poliomyelitis vaccine problems A further important factor reported by Dr G D Zasukhina (Moscow) was that virus grown in tissue culture with a deficient medium was less antigenic than virus grown in a rich medium

The maintenance of the tick-borne viruses in Nature is still not completely understood The course of infection in an experimental animal, the laboratory mouse, was studied by Dr P Albrecht (Bratislava) in an elegant series of experiments based on the use of fluorescent antibody techniques Other animals which may be infected in Nature include bats and lizards (Dr J Rehácèk, Dr J Nosek, and Dr M Grešiková, Bratislava), domestic ducks (Dr E Ernek, Bratislava), and coots (Prof H A E van Tongeren, Leiden) Much remains to be learned about the natural history of this group of viruses Although the great majority of infections are transmitted by the bites of infected ticks, mechanical transmission by mosquitoes (Dr Z Zotowski and Dr Z Wroblewska-Mularczykowa, Warsaw) or fleas (Dr K Heyberger, Dr A Smetana, and Dr B Rosicky, Prague) may play some small part in the local spread of infection, and infection by the ingestion of milk from infected goats, sheep, and cattle is now well established The many factors which influence the natural history of viruses of the tick-borne encephalitis complex were ably reviewed by Dr T H Work (New York)

The full proceedings of the symposium will be published by the printing house of the Czechoslovak Academy of Sciences and this volume will be an authoritative summary of all present knowledge of this important group of viruses The organisers are to be congratulated on calling together the participants and drawing forth such a full and lively exchange of ideas

In England Now

A Running Commentary by Peripatetic Correspondents

ATHEROSCLEROSIS among senior consultants is to be expected and, within reasonable limits, is perhaps right and proper But when it strikes among your contemporaries—chaps you were at school with—complacency is shattered So I bought a bicycle, for has it not been clearly shown by the work of whoever it was that exercise and coronaries were negatively correlated? Admittedly the idea was not entirely my own Not long ago I chanced on a visiting physician of some eminence, washing himself down in the hospital cloakroom He explained that he had just pedalled over from Fulham, a good fourteen miles away

Choice of velocipede was easier than I expected, for there was only one secondhand machine of my size, and when the handlebars had been changed (the old ones scraped the ground) I was left with a good bargain My early experience was salutary 14 years of motoring had involved different (if any) muscles and the saddle impinged on areas of my big-end which I had long forgotten Life on the roads as a glorified pedestrian seemed very different from the world of motorists, and it was most unnatural to have to stop at red lights But I persevered and rode daily to and from hospital As my reflexes, quadriceps, and some callosities developed appropriately, travelling suddenly became much more interesting Territory I had motored over a thousand times yielded unnoticed gems of architecture or nuances of gradient The prevailing wind started to play a part in my life I turned again to Nature and the basic things of life without which a man's spiritual development cannot take place—such as irritable little dogs, midges, and rain down the back of your neck Also you get a closer look at blondes in the bus queue Even securing the aid of a bicycle shop was a new experience, no garage has charged me as little as 2s for anything

Yes, cycling has reopened a dimension in my life Surprising what a few miles a day will do My weight is down, muscles are up, wind is longer, mind clearer, and waist more waisted It has been a wonderful week to recall, as I drive to my hospital with the heater on, listening to the radio

* * *

The Comet journey to New York was a revelation in quietness, and in the extraordinary deep blue of the sky at 40,000 ft

Lima to La Paz was more spectacular than I had imagined After 500 miles of Peruvian desert, with the snowcapped Andes visible from 100 miles away, we went 200 miles east at 18,000 ft, just clearing the pass between the peaks The main impression is the extraordinary colour Over Peru it was an orange brown, with the river beds looking like skeletons of leaves pressed in grandmother's book Then came a range of colours like those seen near the waste heaps of a chemical works, with greens and blues and greys and yellows But since there is the largest deposit of minerals in the world here, perhaps it is no wonder The magnitude of the scenery surpasses anything I saw in Tibet, though perhaps that's not quite fair since I've travelled more here But in an hour or so we went by jeep past snow-covered llamas in the frosty morning, down a series of hair-pin bends dug out of a mountainside at 10° to the vertical at times, until we came to a deep valley with bananas and apples and oranges growing Every half mile or so there are little crosses to mark a too enthusiastic driver, because there are no walls or edges to the road

* * *

The practice of medicine in a foreign country is full of unexpected little quandaries and hazards It's a commonplace that one's knowledge of anatomy dwindles rapidly from the day of passing the M B, but it's not until you have to ask someone in a detailed way about their symptoms in a foreign language that you fully realise how many parts the body has And different languages imply, so often, different points of view, for instance, we are taught in school that *s'asseoir* means *to sit down*, yet if your patient is lying flat and you want him to sit up you say *asseyez-vous* Again, the French do not make quite the same distinction in their language as we do in ours between pain and grief, *douleur* means both Somewhere since Malory wrote about the dolorous wounds of Arthur's knights, we have apparently forgotten that grief may be the real trouble underlying a patient's complaints of pain Perhaps the trickiest problem one encounters in examining a patient abroad is that of vocal fremitus in the chest Each of us solves this in his own way and one musn't be too rigid about it all It would perhaps be a mistake to carry too far the customs of the Old Country into Basutoland where, I'm told, the word for 99 is Machoumearobilengmonoolemongametsoarobilengmonoolemong

* * *

Reading the remarks of my colleague, lately of Lambeth, about the neighbours who persisted in addressing him as "Mister", I wondered whether he invariably refers to himself as "Doctor" Outside working hours I reserve it for certain well-defined occasions One of these is when making appointments at the hairdressers There by suggesting that I am terribly busy and liable to be called away at any moment, it facilitates excuses for missed appointments and enables me to get a quick shampoo and set at short notice Again, I always use the title when I am asked to sign my name and address on the back of cheques, under these circumstances any extra evidence of respectability is of great help

Lately it saved me from a good deal of inconvenience My scooter was stolen from a part of London many miles from where I live Late the same evening, the police rang to say that they had found it, and would I come to the station at once to collect it and sign the charge-sheet Grateful but weary, I said that I would be there as soon as possible in view of the distance and the hour "You wait there, Doctor, and we'll send a car," the station officer assured me, doubtless with the idea that at any moment I might be called upon to save a life, and the car duly arrived

There are times, of course, when I deliberately avoid the title, but my landlady disapproves strongly of any attempts at dissimulation If people ask for me on the phone as "Miss " or use my Christian name, I hear her answer sternly, "I'll see if The Doctor is in"

* * *

Comparative textual criticism can be fun Study of Baedeker's post-war (1958) guide to Austria and the 1929 edition provides a revealing gombarison—sorry, comparison Though the familiar red cover with gold lettering is retained, it is no longer teutonically tubby but svelte It contains 294 pages compared to 518, 100 of which were devoted to "Budapest, Prague and the north Bohemian spas", now omitted (Though Hungary and Czechoslovakia had been independent countries for ten years, one would hardly gather it from the 1929 edition) The present edition, now called an autoguide, is streamlined in other ways besides format for instance, we no longer have blow-by-blow accounts of museums and picture-galleries with exhibits thought worthy of notice by Herr Karl mentioned in each room There is less ancient history and esoteric information thus we are no longer told that the Dragon Fountain or Lindwurmbrunnen in Klagenfurt is made of "chorite schist" but I was glad to see that the tablet commemorating Emanuel Hermann (1839–1902), "who invented the postcard", is still mentioned Nor are there detailed tours of each town, starting from the railway station, but much clearer plans with "sight-seeing tours" and "through routes" In fact, modern travel is clearly no longer designed either to broaden the mind or flatten the feet But nostalgia is catered for by the occasional survival of some of the classical phrases such as "Gasthof Lukashof, plain but well spoken of", still recalling one's aunt or members of the Women's Institute

* * *

O, my Luve's like a red, red rose
I hope it's nothing catching

faculty? Then indeed the " dissensions and bankruptcy " of which you warn us might well become a reality

Our seniors often tell us that there is no advantage to them from either course, and that they are only concerned to provide for the younger pathologists in whose hands the future lies At the same time they tend, perhaps, to ignore the experience of most of those who discuss such matters with these younger pathologists, and find that they are mostly in favour of a College The young men do not seem to be afraid of starting in a small way provided that they can feel genuinely independent and not a sort of appendage to another college Their " image " of pathology is of a subject which is of real importance in its own right and which can therefore expect its own separate and individual organisation

If we are to build surely for the future, independence is the only safe choice When I have reached retiring age, I do not want my juniors to be able to say to me " You and your colleagues made a fine mess of things in 1960 Here we are stuck in the College of Physicians where we are not really happy, but it will be very difficult to break away now If you had only made the effort to form a College it would be well established by now Did you *have* to choose the easy way? Couldn't you see just a little way in front of your noses?"

Yours,

G G

Symposium

TICK-BORNE ENCEPHALITIS VIRUSES

FROM A CORRESPONDENT

THE Institute of Virology of the Czechoslovak Academy of Sciences acted as hosts to virologists from eleven different countries during a four-day symposium last month on the biology of viruses of the tick-borne encephalitis complex The meetings were held in delightful surroundings at the House of Scientists at Smolenice, near Bratislava Representatives from almost all the major groups working on this subject were present, and the symposium provided an unusual opportunity for workers from many different disciplines to pool information and exchange ideas in a common approach In Britain, human infections with louping-ill virus do not present a serious public-health problem, but in Central Europe, Scandinavia, U S S R, and India viruses of the tick-borne encephalitis group are a serious menace The recent recognition of human infections with viruses of this group in Canada[1,2] and the U S A[3] extends the area in which these viruses are known

Dr J CASALS (New York) showed how the tick-borne viruses were placed with yellow fever and some twenty other arthropod-borne viruses into the serological group B on the basis of antigenic relationships In the past, the tick-borne encephalitis viruses have been considered a homogeneous group in spite of wide differences in the disease patterns they produced in different parts of the world Dr D H CLARKE (New York) showed that they could be divided into six antigenic subgroups on the basis of hæmagglutination inhibition tests with absorbed sera and by agar-gel precipitin tests The six subgroups were represented by the classical far-eastern Russian spring-summer encephalitis (R S S E), louping ill, Omsk hæmorrhagic fever, Kyasanur Forest disease,[4] Malayan tick-borne Langat virus, and Central European tick-borne encephalitis which included Czechoslovakian, Austrian, Finnish, Polish, Swedish, and Yugoslavian strains, as well as strains from European U S S R The recently described North American Powassan virus had not yet been examined by these techniques These antigenic differences were important because they explained the reported failure of R S S E vaccine to protect humans (Dr P N BHATT, Poona) or mice (Dr L DANEŠ, Prague) against infection with the virus of Kyasanur Forest disease

As in other branches of virology, tissue-culture techniques were gradually replacing older methods for the titration of viruses and for the detection of neutralising antibodies The use of a plaque technique for the titration of tick-borne encephalitis viruses was described by Dr J S PORTERFIELD (London) and was applied by Dr V MAYER, Dr J ZAVADÁ, and Dr R SKODA (Bratislava) to Central European strains Dr BHATT reported that chick fibroblast cultures were as satisfactory as mice for the primary isolation of Kyasanur Forest disease virus Czechoslovak workers preferred a two-stage process—primary isolation in tissue-culture cells which were later shown to be infected by virtue of their resistance to a challenge virus Neutralising antibodies were detected by a metabolic inhibition test carried out in Hela cells (Dr H LÍBIKOVÁ and Dr J VILČEK, Bratislava), by plaque inhibition (Dr J S PORTERFIELD, London), or by the direct inhibition of cytopathic effect in Hela cells (Dr E MOLNAR, Budapest) or in pig kidney cells (Dr D MÁLKOVÁ, Dr Z MARHOUL, Dr V FRAŇKOVÁ, and Dr V ČERNY, Prague)

Vaccines derived from formalinised mouse brain had been used for many years in the U S S R (Prof E N LEVKOVICH, Moscow, Prof A A SMORODINSTEV, and Dr V I ILYENKO, Leningrad) and formalin-inactivated louping-ill vaccine had been used to protect laboratory personnel (Dr D G FF EDWARD, Beckenham) and domestic animals (Dr D BLASCOVIČ and others, Bratislava) Attempts at producing a vaccine from virus grown in tissue culture were reported from Prague (Dr R BENDA and Dr DANES), from Budapest (Dr E MOLNAR), and from the U S S R The major difficulty was to guarantee complete destruction of infectivity without at the same time reducing the antigenicity of the vaccine There were many parallels with the poliomyelitis vaccine problems A further important factor reported by Dr G D ZASUKHINA (Moscow) was that virus grown in tissue culture with a deficient medium was less antigenic than virus grown in a rich medium

The maintenance of the tick-borne viruses in Nature is still not completely understood The course of infection in an experimental animal, the laboratory mouse, was studied by Dr P ALBRECHT (Bratislava) in an elegant series of experiments based on the use of fluorescent antibody techniques Other animals which may be infected in Nature include bats and lizards (Dr J ŘEHÁCĚK, Dr J NOSEK, and Dr M GREŠIKOVÁ, Bratislava), domestic ducks (Dr E ERNEK, Bratislava), and coots (Prof H A E VAN TONGEREN, Leiden) Much remains to be learned about the natural history of this group of viruses Although the great majority of infections are transmitted by the bites of infected ticks, mechanical transmission by mosquitoes (Dr Z ZOTOWSKI and Dr Z WROBLEWSKA-MULARCZYKOWA, Warsaw) or fleas (Dr K HEYBERGER, Dr A SMETANA, and Dr B ROSICKÝ, Prague) may play some small part in the local spread of *infection*, and infection by the ingestion of milk from infected goats, sheep, and cattle is now well established The many factors which influence the natural history of viruses of the tick-borne encephalitis complex were ably reviewed by Dr T H WORK (New York)

The full proceedings of the symposium will be published by the printing house of the Czechoslovak Academy of Sciences and this volume will be an authoritative summary of all present knowledge of this important group of viruses The organisers are to be congratulated on calling together the participants and drawing forth such a full and lively exchange of ideas

In England Now

A Running Commentary by Peripatetic Correspondents

ATHEROSCLEROSIS among senior consultants is to be expected and, within reasonable limits, is perhaps right and proper. But when it strikes among your contemporaries—chaps you were at school with—complacency is shattered. So I bought a bicycle, for has it not been clearly shown by the work of whoever it was that exercise and coronaries were negatively correlated? Admittedly the idea was not entirely my own. Not long ago I chanced on a visiting physician of some eminence, washing himself down in the hospital cloakroom. He explained that he had just pedalled over from Fulham, a good fourteen miles away.

Choice of velocipede was easier than I expected, for there was only one secondhand machine of my size, and when the handlebars had been changed (the old ones scraped the ground) I was left with a good bargain. My early experience was salutary: 14 years of motoring had involved different (if any) muscles and the saddle impinged on areas of my big-end which I had long forgotten. Life on the roads as a glorified pedestrian seemed very different from the world of motorists, and it was most unnatural to have to stop at red lights. But I persevered and rode daily to and from hospital. As my reflexes, quadriceps, and some callosities developed appropriately, travelling suddenly became much more interesting. Territory I had motored over a thousand times yielded unnoticed gems of architecture or nuances of gradient. The prevailing wind started to play a part in my life. I turned again to Nature and the basic things of life without which a man's spiritual development cannot take place—such as irritable little dogs, midges, and rain down the back of your neck. Also you get a closer look at blondes in the bus queue. Even securing the aid of a bicycle shop was a new experience; no garage has charged me as little as 2s. for anything.

Yes, cycling has reopened a dimension in my life. Surprising what a few miles a day will do. My weight is down, muscles are up, wind is longer, mind clearer, and waist more waisted. It has been a wonderful week to recall, as I drive to my hospital with the heater on, listening to the radio.

The Comet journey to New York was a revelation in quietness, and in the extraordinary deep blue of the sky at 40,000 ft.

Lima to La Paz was more spectacular than I had imagined. After 500 miles of Peruvian desert, with the snowcapped Andes visible from 100 miles away, we went 200 miles east at 18,000 ft., just clearing the pass between the peaks. The main impression is the extraordinary colour. Over Peru it was an orange brown, with the river beds looking like skeletons of leaves pressed in grandmother's book. Then came a range of colours like those seen near the waste heaps of a chemical works, with greens and blues and greys and yellows. But since there is the largest deposit of minerals in the world here, perhaps it is no wonder. The magnitude of the scenery surpasses anything I saw in Tibet, though perhaps that's not quite fair since I've travelled more here. But in an hour or so we went by jeep past snow-covered llamas in the frosty morning, down a series of hair-pin bends dug out of a mountainside at 10° to the vertical at times, until we came to a deep valley with bananas and apples and oranges growing. Every half mile or so there are little crosses to mark a too enthusiastic driver, because there are no walls or edges to the road.

* * *

The practice of medicine in a foreign country is full of unexpected little quandaries and hazards. It's a commonplace that one's knowledge of anatomy dwindles rapidly from the day of passing the M.B., but it's not until you have to ask someone in a detailed way about their symptoms in a foreign language that you fully realise how many parts the body has. And different languages imply, so often, different points of view; for instance, we are taught in school that *s'asseoir* means *to sit down*, yet if your patient is lying flat and you want him to sit up you say *asseyez-vous*. Again, the French do not make quite the same distinction in their language as we do in ours between pain and grief; *douleur* means both. Somewhere since Malory wrote about the dolorous wounds of Arthur's knights, we have apparently forgotten that grief may be the real trouble underlying a patient's complaints of pain. Perhaps the trickiest problem one encounters in examining a patient abroad is that of vocal fremitus in the chest. Each of us solves this in his own way and one musn't be too rigid about it all. It would perhaps be a mistake to carry too far the customs of the Old Country into Basutoland where, I'm told, the word for 99 is Machoumearobilengmonoolemongametsoarobilengmonoolemong.

* * *

Reading the remarks of my colleague, lately of Lambeth, about the neighbours who persisted in addressing him as “Mister”, I wondered whether he invariably refers to himself as “Doctor”. Outside working hours I reserve it for certain well-defined occasions. One of these is when making appointments at the hairdressers. There by suggesting that I am terribly busy and liable to be called away at any moment, it facilitates excuses for missed appointments and enables me to get a quick shampoo and set at short notice. Again, I always use the title when I am asked to sign my name and address on the back of cheques; under these circumstances any extra evidence of respectability is of great help.

Lately it saved me from a good deal of inconvenience. My scooter was stolen from a part of London many miles from where I live. Late the same evening, the police rang to say that they had found it, and would I come to the station at once to collect it and sign the charge-sheet. Grateful but weary, I said that I would be there as soon as possible in view of the distance and the hour. “You wait there, Doctor, and we'll send a car,” the station officer assured me, doubtless with the idea that at any moment I might be called upon to save a life, and the car duly arrived.

There are times, of course, when I deliberately avoid the title, but my landlady disapproves strongly of any attempts at dissimulation. If people ask for me on the phone as “Miss ” or use my Christian name, I hear her answer sternly, “I'll see if The Doctor is in.”

* * *

Comparative textual criticism can be fun. Study of Baedeker's post-war (1958) guide to Austria and the 1929 edition provides a revealing gombarison—sorry, comparison. Though the familiar red cover with gold lettering is retained, it is no longer teutonically tubby but svelte. It contains 294 pages compared to 518, 100 of which were devoted to “Budapest, Prague and the north Bohemian spas”, now omitted. (Though Hungary and Czechoslovakia had been independent countries for ten years, one would hardly gather it from the 1929 edition.) The present edition, now called an autoguide, is streamlined in other ways besides format: for instance, we no longer have blow-by-blow accounts of museums and picture-galleries with exhibits thought worthy of notice by Herr Karl mentioned in each room. There is less ancient history and esoteric information: thus we are no longer told that the Dragon Fountain or Lindwurmbrunnen in Klagenfurt is made of “chorite schist” but I was glad to see that the tablet commemorating Emanuel Hermann (1839–1902), “who invented the postcard”, is still mentioned. Nor are there detailed tours of each town, starting from the railway station, but much clearer plans with “sight-seeing tours” and “through routes”. In fact, modern travel is clearly no longer designed either to broaden the mind or flatten the feet. But nostalgia is catered for by the occasional survival of some of the classical phrases such as “Gasthof Lukashof, plain but well spoken of”, still recalling one's aunt or members of the Women's Institute.

Symposium

TICK-BORNE ENCEPHALITIS VIRUSES

FROM A CORRESPONDENT

The Institute of Virology of the Czechoslovak Academy of Sciences acted as hosts to virologists from eleven different countries during a four-day symposium last month on the biology of viruses of the tick-borne encephalitis complex The meetings were held in delightful surroundings at the House of Scientists at Smolenice, near Bratislava Representatives from almost all the major groups working on this subject were present, and the symposium provided an unusual opportunity for workers from many different disciplines to pool information and exchange ideas in a common approach In Britain, human infections with louping-ill virus do not present a serious public-health problem, but in Central Europe, Scandinavia, U S S R, and India viruses of the tick-borne encephalitis group are a serious menace The recent recognition of human infections with viruses of this group in Canada[1 2] and the U S A[3] extends the area in which these viruses are known

Dr J Casals (New York) showed how the tick-borne viruses were placed with yellow fever and some twenty other arthropod-borne viruses into the serological group B on the basis of antigenic relationships In the past, the tick-borne encephalitis viruses have been considered a homogeneous group in spite of wide differences in the disease patterns they produced in different parts of the world Dr D H Clarke (New York) showed that they could be divided into six antigenic subgroups on the basis of hæmagglutination inhibition tests with absorbed sera and by agar-gel precipitin tests The six subgroups were represented by the classical far-eastern Russian spring-summer encephalitis (R S S E), louping ill, Omsk hæmorrhagic fever, Kyasanur Forest disease,[4] Malayan tick-borne Langat virus, and Central European tick-borne encephalitis which included Czechoslovakian, Austrian, Finnish, Polish, Swedish, and Yugoslavian strains, as well as strains from European U S S R The recently described North American Powassan virus had not yet been examined by these techniques These antigenic differences were important because they explained the reported failure of R S S E vaccine to protect humans (Dr P N Bhatt, Poona) or mice (Dr L Daneš, Prague) against infection with the virus of Kyasanur Forest disease

As in other branches of virology, tissue-culture techniques were gradually replacing older methods for the titration of viruses and for the detection of neutralising antibodies The use of a plaque technique for the titration of tick-borne encephalitis viruses was described by Dr J S Porterfield (London) and was applied by Dr V Mayer, Dr J Zavadá, and Dr R Šķoda (Bratislava) to Central European strains Dr Bhatt reported that chick fibroblast cultures were as satisfactory as mice for the primary isolation of Kyasanur Forest disease virus Czechoslovak workers preferred a two-stage process—primary isolation in tissue-culture cells which were later shown to be infected by virtue of their resistance to a challenge virus Neutralising antibodies were detected by a metabolic inhibition test carried out in Hela cells (Dr H Líbiková and Dr J Vilček, Bratislava), by plaque inhibition (Dr J S Porterfield, London), or by the direct inhibition of cytopathic effect in Hela cells (Dr E Molnar, Budapest) or in pig kidney cells (Dr D Málková, Dr Z Marhoul, Dr V Fraňková, and Dr V Černy, Prague)

Vaccines derived from formalinised mouse brain had been used for many years in the U S S R (Prof E N Levkovich, Moscow, Prof A A Smorodinstev, and Dr V I Ilyenko, Leningrad) and formalin-inactivated louping-ill vaccine had been used to protect laboratory personnel (Dr D G ff Edward, Beckenham) and domestic animals (Dr D Blascovič and others, Bratislava) Attempts at producing a vaccine from virus grown in tissue culture were reported from Prague (Dr R Benda and Dr Danes), from Budapest (Dr E Molnar), and from the U S S R The major difficulty was to guarantee complete destruction of infectivity without at the same time reducing the antigenicity of the vaccine There were many parallels with the poliomyelitis vaccine problems A further important factor reported by Dr G D Zasukhina (Moscow) was that virus grown in tissue culture with a deficient medium was less antigenic than virus grown in a rich medium

The maintenance of the tick-borne viruses in Nature is still not completely understood The course of infection in an experimental animal, the laboratory mouse, was studied by Dr P Albrecht (Bratislava) in an elegant series of experiments based on the use of fluorescent antibody techniques Other animals which may be infected in Nature include bats and lizards (Dr J Reháček, Dr J Nosek, and Dr M Grešiková, Bratislava), domestic ducks (Dr E Ernek, Bratislava), and coots (Prof H A E van Tongeren, Leiden) Much remains to be learned about the natural history of this group of viruses Although the great majority of infections are transmitted by the bites of infected ticks, mechanical transmission by mosquitoes (Dr Z Zotowski and Dr Z Wroblewska-Mularczykowa, Warsaw) or fleas (Dr K Heyberger, Dr A Smetana, and Dr B Rosický, Prague) may play some small part in the local spread of infection, and infection by the ingestion of milk from infected goats, sheep, and cattle is now well established The many factors which influence the natural history of viruses of the tick-borne encephalitis complex were ably reviewed by Dr T H Work (New York)

The full proceedings of the symposium will be published by the printing house of the Czechoslovak Academy of Sciences and this volume will be an authoritative summary of all present knowledge of this important group of viruses The organisers are to be congratulated on calling together the participants and drawing forth such a full and lively exchange of ideas

In England Now

A Running Commentary by Peripatetic Correspondents

ATHEROSCLEROSIS among senior consultants is to be expected and, within reasonable limits, is perhaps right and proper. But when it strikes among your contemporaries—chaps you were at school with—complacency is shattered. So I bought a bicycle, for has it not been clearly shown by the work of whoever it was that exercise and coronaries were negatively correlated? Admittedly the idea was not entirely my own. Not long ago I chanced on a visiting physician of some eminence, washing himself down in the hospital cloakroom. He explained that he had just pedalled over from Fulham, a good fourteen miles away.

Choice of velocipede was easier than I expected, for there was only one secondhand machine of my size, and when the handlebars had been changed (the old ones scraped the ground) I was left with a good bargain. My early experience was salutary. 14 years of motoring had involved different (if any) muscles and the saddle impinged on areas of my big-end which I had long forgotten. Life on the roads as a glorified pedestrian seemed very different from the world of motorists, and it was most unnatural to have to stop at red lights. But I persevered and rode daily to and from hospital. As my reflexes, quadriceps, and some callosities developed appropriately, travelling suddenly became much more interesting. Territory I had motored over a thousand times yielded unnoticed gems of architecture or nuances of gradient. The prevailing wind started to play a part in my life. I turned again to Nature and the basic things of life without which a man's spiritual development cannot take place—such as irritable little dogs, midges, and rain down the back of your neck. Also you get a closer look at blondes in the bus queue. Even securing the aid of a bicycle shop was a new experience, no garage has charged me as little as 2s. for anything.

Yes, cycling has reopened a dimension in my life. Surprising what a few miles a day will do. My weight is down, muscles are up, wind is longer, mind clearer, and waist more waisted. It has been a wonderful week to recall, as I drive to my hospital with the heater on, listening to the radio.

* * *

The Comet journey to New York was a revelation in quietness, and in the extraordinary deep blue of the sky at 40,000 ft.

Lima to La Paz was more spectacular than I had imagined. After 500 miles of Peruvian desert, with the snowcapped Andes visible from 100 miles away, we went 200 miles east at 18,000 ft., just clearing the pass between the peaks. The main impression is the extraordinary colour. Over Peru it was an orange brown, with the river beds looking like skeletons of leaves pressed in grandmother's book. Then came a range of colours like those seen near the waste heaps of a chemical works, with greens and blues and greys and yellows. But since there is the largest deposit of minerals in the world here, perhaps it is no wonder. The magnitude of the scenery surpasses anything I saw in Tibet, though perhaps that's not quite fair since I've travelled more here. But in an hour or so we went by jeep past snow-covered llamas in the frosty morning, down a series of hair-pin bends dug out of a mountainside at 10° to the vertical at times, until we came to a deep valley with bananas and apples and oranges growing. Every half mile or so there are little crosses to mark a too enthusiastic driver, because there are no walls or edges to the road.

* * *

The practice of medicine in a foreign country is full of unexpected little quandaries and hazards. It's a commonplace that one's knowledge of anatomy dwindles rapidly from the day of passing the M.B., but it's not until you have to ask someone in a detailed way about their symptoms in a foreign language that you fully realise how many parts the body has. And different languages imply, so often, different points of view, for instance, we are taught in school that *s'asseoir* means *to sit down*, yet if your patient is lying flat and you want him to sit up you say *asseyez-vous*. Again, the French do not make quite the same distinction in their language as we do in ours between pain and grief, *douleur* means both. Somewhere since Malory wrote about the dolorous wounds of Arthur's knights, we have apparently forgotten that grief may be the real trouble underlying a patient's complaints of pain. Perhaps the trickiest problem one encounters in examining a patient abroad is that of vocal fremitus in the chest. Each of us solves this in his own way and one musn't be too rigid about it all. It would perhaps be a mistake to carry too far the customs of the Old Country into Basutoland where, I'm told, the word for 99 is Machoumearobilengmonoolemongametsoarobilengmonoolemong.

* * *

Reading the remarks of my colleague, lately of Lambeth, about the neighbours who persisted in addressing him as "Mister", I wondered whether he invariably refers to himself as "Doctor". Outside working hours I reserve it for certain well-defined occasions. One of these is when making appointments at the hairdressers. There by suggesting that I am terribly busy and liable to be called away at any moment, it facilitates excuses for missed appointments and enables me to get a quick shampoo and set at short notice. Again, I always use the title when I am asked to sign my name and address on the back of cheques, under these circumstances any extra evidence of respectability is of great help.

Lately it saved me from a good deal of inconvenience. My scooter was stolen from a part of London many miles from where I live. Late the same evening, the police rang to say that they had found it, and would I come to the station at once to collect it and sign the charge-sheet. Grateful but weary, I said that I would be there as soon as possible in view of the distance and the hour. "You wait there, Doctor, and we'll send a car," the station officer assured me, doubtless with the idea that at any moment I might be called upon to save a life, and the car duly arrived.

There are times, of course, when I deliberately avoid the title, but my landlady disapproves strongly of any attempts at dissimulation. If people ask for me on the phone as "Miss   " or use my Christian name, I hear her answer sternly, "I'll see if The Doctor is in."

* * *

Comparative textual criticism can be fun. Study of Baedeker's post-war (1958) guide to Austria and the 1929 edition provides a revealing gombarison—sorry, comparison. Though the familiar red cover with gold lettering is retained, it is no longer teutonically tubby but svelte. It contains 294 pages compared to 518, 100 of which were devoted to "Budapest, Prague and the north Bohemian spas", now omitted. (Though Hungary and Czechoslovakia had been independent countries for ten years, one would hardly gather it from the 1929 edition.) The present edition, now called an autoguide, is streamlined in other ways besides format: for instance, we no longer have blow-by-blow accounts of museums and picture-galleries with exhibits thought worthy of notice by Herr Karl mentioned in each room. There is less ancient history and esoteric information: thus we are no longer told that the Dragon Fountain or Lindwurmbrunnen in Klagenfurt is made of "chorite schist" but I was glad to see that the tablet commemorating Emanuel Hermann (1839–1902), "who invented the postcard", is still mentioned. Nor are there detailed tours of each town, starting from the railway station, but much clearer plans with "sight-seeing tours" and "through routes". In fact, modern travel is clearly no longer designed either to broaden the mind or flatten the feet. But nostalgia is catered for by the occasional survival of some of the classical phrases such as "Gasthof Lukashof, plain but well spoken of", still recalling one's aunt or members of the Women's Institute.

I hope it's nothing catching.

Letters to the Editor

FUTURE ORGANISATION OF PATHOLOGISTS

SIR,—A voting paper is about to be circulated to pathologists asking them to record their opinion for or against a division of pathology within the Royal College of Physicians, or a new College of Pathology

We have for many years been concerned with research in pathology and with the training of pathologists, and believe that a higher examination based on a background of suitable training is essential to ensure that candidates either for hospital or academic appointments have acquired a reasonable grounding in their subject

We both write as past presidents of the Association of Clinical Pathologists, who have been openly critical of the procrastination of the Royal College, but who are satisfied that the suggestions now put forward by it are what is required Undoubtedly, the Royal College has been unduly tardy in making any suggestions, but the present generous and unequivocal terms make amends

It is generally agreed that in modern conditions the membership is an unsuitable examination for pathologists In the time available the techniques of clinical examination and of pathology cannot both be mastered

We welcome the opportunity of still closer cooperation with our clinical colleagues Not only are they progressively more dependent on us for confirmation of diagnosis, or indeed in many cases for provision of all the important data, but, reciprocally, we also are dependent on their acumen and powers of selection for our daily interests

We have long believed that what is needed is

(1) A higher qualification of the same status as the M R C P and F R C S

(2) An academic centre which would uphold the standards of pathology and help in maintaining good standards of training in pathologists

(3) A body to speak for pathologists

In our opinion the suggestion of the Royal College satisfies these requirements We believe that unless this opportunity is accepted there will be a very long delay before we realise our ambitions

JOAN TAYLOR
R J V PULVERTAFT

London

SIR,—Much has been said and written on this subject by the more learned and senior practitioners of our specialty, but little by the juniors As one of their number may I put forward three points

The primary reason for any alteration in the present position is to ensure recognition of the status of pathologists, despite the fact that a man's status depends above all upon his personality and the quality of his work, and only secondarily upon his qualifications Higher qualifications, however, are necessary to prove adequate training in one's own specialty for promotion to consultant or similar grade, and the institution of a specialist examination in pathology, of the highest standard, is now urgently required To the pathologist in training it is the most important facet of the present discussions The expenditure of time and work by those who aspire to the membership of one of the Royal Colleges of Physicians has been eloquently described by Professor Cappell in his presidential address [1] to the Association of Clinical Pathologists It is certain that only the qualification offered by the Royal College of Physicians will have the immediate high standing required to divert them from such examinations

The finances of the new organisation are of particular interest to impecunious registrars and lecturers It has been said that the provision and maintenance of any reasonable building will cost each member an initial donation of about £100 and an annual subscription of up to £25! Some of us may not be able to find such a sum Are we to be excluded from the college until we are senior enough to afford the subscription, and if so will we ever achieve the seniority? However, we are assured that industry and various benevolent foundations will provide the necessary funds Even if the money is forthcoming, I do not believe we can justify spending such vast sums on establishing a college, when there are so many research projects urgently needing finance Would our money not be better spent on research on acute leukæmia in children or even coronary disease in pathologists than upon a building? £100,000 would buy a lot of knowledge of disease—could we not devote our benefactions (if any) to establishing a series of research fellowships rather than a college?

If a College of Pathology is to be founded then I believe it must be as broadly based as possible and must be open freely to all those who work in and around the subject, scientist or doctor, whether academic or clinical Pathology is neither practised nor advanced solely by those on the Medical Register However, in a Faculty of the Royal College of Physicians it would be logical to restrict full membership to the medically qualified

The College of Physicians of London is a body of the highest standing and to be called a physician is no dishonour I hope, with Peter Davey,[2] that a Faculty will be established They offer us more than does an independent college in the foreseeable future, and at less cost The generosity of their terms puts us in an immensely strong position, and we can always withdraw

Finally, may I suggest abandonment of the term "Division of Pathology", for the words come uncomfortably close to the truth

London, S W 15 P O'GORMAN

*** Another view on this subject is given on p 1025 in a letter from the Widdicombe File —ED L

ATHEROSCLEROSIS AND CORONARY HEART-DISEASE

SIR,—Surely your correspondents are arguing on points of semantics rather than pathology As you, Sir, rightly pointed out last year,[3] patients do not suffer or die from coronary disease, but from the consequences of myocardial ischæmia, which may be acute, chronic, or spasmodic I have always held that one of the best classifications of disease causation, is that which we learned at our obstetrician's knee, of which a part ran—faults in the powers, faults in the passages, faults in the passenger Myocardial ischæmia may be due to faults in the power of the heart's action, faults in the coronary passages whether narrowed or occluded by what you will, or faults in the passenger—the blood, which may be deficient in oxygen-carrying capacity, or contain a substance noxious to the myocardium

In spite of the welter of investigations on atheroma and degenerative heart-disease, we remain remarkably ignorant as to the frequency, degree, and type of myocardial ischæmic change to be found at death in the population as a whole, and without this many of our deductions in this field are insecure I believe that a study, almost completed here by Dr C J Schwartz and Dr J R A Mitchell, will give us this information, as far as the current Oxford postmortem population is concerned, and may encourage others to carry out comparable investigations elsewhere

---

[1] Lancet, Oct 15 1960, p 863

[2] See ibid Oct 22 1960, p 921

[3] Lancet 1959 ii, 863

No-one would dispute that one may find coronary narrowing or occlusion in hearts from persons of all ages, yet it remains that in a high proportion of elderly persons, ischæmic myocardial lesions occur, which are quite different in character from those usually seen in the younger age-groups, for example, there is the condition which Linzbach called reticular myocardial necrosis, but unhappily this is a sphere of cardiac pathology which to a large extent is unexplored

Turning to the Registrar-General's statistics, we find some curious features

England and Wales Crude Death rate to a million living

	1940	*1949*	*1958*
Arteriosclerotic heart-disease, including coronary disease (I S C. 420)	573	1093	1863
Myocardial degeneration with arteriosclerosis (I S C. 442 1)	467	617	532
Other myocardial degeneration (I.S C 422 2)	1548	1274	656
Total degenerative heart-disease (I.S C. 420 — 442 1 2	2588	2984	3051

As everyone knows, the death-rate attributed to " arteriosclerotic heart-disease and coronary disease " has increased more than threefold in the past eighteen years, but " myocardial degeneration with arteriosclerosis " has hardly changed at all and " other myocardial degeneration " has fallen to a third, so that if one groups together the rubrics that can be regarded as representing ischæmic heart-disease (I S C 420, 422 1, 422 2), the rate has only increased by a fifth, which is little more than is to be anticipated in view of the increased expectation of life I am, of course, as aware of the defects of comparison of crude death-rates as against standardised mortality ratios, as I am of the answer which John Graunt found to his question, why there were so few deaths attributed to the Pox in the Bills of Mortality Nevertheless, it might be worth while, for those who believe, that by feeding rabbits or men on unnatural diets, they will determine what factors in modern life have caused this spectacular increase in deaths attributed to " coronary disease ', to try and find out what are the factors which have caused the almost equally spectacular decrease in deaths attributed to " myocardial degeneration "

When we look at the age-differences, the Registrar-General's tables reveal another curious feature

England and Wales Age differences

	Proportion of Deaths Over 65			*No of Deaths 1958*		
	1940	*1949*	*1958*	*<65 yr*	*65 + yr*	*Total*
All causes	53%	63%	68%			
Arteriosclerotic heart-disease including coronary disease (I S C. 420)	55%	65%	69%	25 962	58,079	84,041
Myocardial degeneration (I.S C. 422)	85%	90%	95%	2195	51 577	53 772

As is to be expected in an ageing population, the proportion of all deaths occurring over 65 is steadily rising, in 1940 it was 53% and in 1958 68%, and the proportions of deaths attributed to arteriosclerotic heart and coronary disease is almost identical (1940 55%, 1958 69%), but of the deaths attributed to myocardial degeneration, 85% occurred at 65 and over, in 1940 and 95% in 1958

Putting this in another way, in 1958 there were 138,000 deaths attributed to " arteriosclerotic heart and coronary disease " and " myocardial degeneration ", of which only 20% occurred under the age of 65 Of these 28,000 deaths under 65, 94% were attributed to arteriosclerotic heart and coronary disease, whereas of the 110,000 deaths over 65, 47% were attributed to myocardial degeneration

There are clearly a number of explanations for this difference, but it must be assumed that certifying doctors consider that there is a fatal form of heart-disease which they designate as " myocardial degeneration " or any of the other inclusion terms in rubric 422, which occurs almost exclusively in persons of 65 and over, and accounts for nearly half of the cases of degenerative heart-disease in this higher age-group

Naturally we have no idea what, if any, are the clinical differences or morbid anatomical lesions in cases attributed to these two rubrics but if there are real differences, other than the whims of nomenclature of the certifying doctors, then it would be in keeping with Dr Acheson's[4] observations

SARCOIDOSIS TREATED WITH CHLOROQUINE

Sir,—I have read with interest Dr Soderstrom's article of Oct 29 in which he described the response of two patients with sarcoidosis to mepacrine He suggested that chloroquine may be used instead of mepacrine

I have treated with chloroquine systemic lupus erythematosus, periarteritis nodosa, Stevens-Johnson syndrome, and other hypersensitivity states since 1953 and rheumatoid arthritis since 1954 [5] [6]

The ætiology of sarcoidosis is still unproven, but there is a fairly strong suggestion that hypersensitivity may again play a part Michael [7] and Cummings,[8] for instance, related sarcoidosis to the chemical constituents of pine pollen

On the assumption that sarcoidosis represented a hypersensitivity state I have treated two cases with chloroquine since 1957

A married woman, aged 32, was first diagnosed as sarcoidosis, involving mainly the lungs, in 1956 when treatment was started with chloroquine sulphate 200 mg t d s This was continued for six months when it was stopped because of pregnancy By then all lung lesions had cleared Her condition was reviewed in 1957 and 1958, when she was quite well and the X-ray films showed clear lung fields

A married woman of 23 was first seen in July, 1957, when she had characteristic sarcoid lesions on her upper arms, trunk, and buttocks, and hilar-gland enlargement Biopsy confirmed the clinical diagnosis The Mantoux test was negative Chloroquine sulphate 200 mg t d s was started in July, 1957 In September, 1957, the hilar enlargement had greatly diminished and the skin lesions subsided In February, 1959, she was entirely symptomless and stopped chloroquine on her own By May, 1959, there was a recurrence of lesions on the right side of her cheek, upper arms, and buttock Chloroquine was immediately re-started, and by July, 1960, the skin lesions had almost completely disappeared and she felt well This patient is still on 200 mg chloroquine sulphate daily

At the international conference on sarcoidosis in Washington, D C , this year several speakers described the beneficial effect of chloroquine in sarcoidosis

Evaluation of any drug for sarcoidosis is difficult because of the fluctuation in the natural history of the disease with frequent spontaneous remissions This was the reason for not publishing my own limited experience of the drug in sarcoidosis If, however, since it appears that more widespread trials of chloroquine in the management of sarcoidosis are carried out in other parts of the world, then even a very limited trial such as Dr Soderstrom's and my own should be made known It is of particular interest that Dr Soderstrom noted selective staining of sarcoid lesions by the antimalarial There is reason to believe that chloroquine, too, has a selective action on the joints in rheumatoid arthritis, as we have found after 18 months' experience with chloroquine injections into rheumatoid arthritic joints (details are about to be published)

HEATSTROKE

Sir,—I must congratulate you on your editorial of Oct 15 Such is the reputation of your journal, however, that unless I take issue with you on a matter of emphasis it may appear that treatment in a special room with refrigerated water, as described by Guthrie and McCraken,[1] is the best and only satisfactory method of treatment I know that special rooms of this nature are provided in the Persian Gulf—but many a heatstroke has been treated successfully with only the minimum of facilities I feel that it would be better to emphasise the principles of treatment rather than the accessories, which are expensive

At the moment there appear to be two schools of thought on treatment one uses refrigerated water or iced baths or iced sheets and the other artificial sweat and forced air movement I am a convert to the second school ever since I encountered shivering as a response to treatment with iced sheets in a patient who was still hyperpyrexial After this I began to reconsider the physics of reducing body temperature

Everyone knows that during treatment it is important not to reduce the temperature to normal limits as this may give rise to shock, and if shock occurs it is very difficult to treat Immersion in an iced bath can be very "shocking" to even a normal individual just jump naked into the Serpentine next January if you wish to contest this point! Immersion in, or spraying with, refrigerated water coils the body by conduction alone and is associated, sooner or later as the body cools, with peripheral vasoconstriction This vasoconstriction converts the skin, with its superficial fat, into a fairly useful insulating layer

Heatstroke is related to cessation of sweating however caused Evaporation of sweat from the skin, by virtue of the latent heat necessary to effect this, rapidly cools the blood flowing through the dilated skin vessels, which then act as a heat exchanger to the internal organs When sweating has ceased it is logical to provide artificial sweat in the form of tepid water and to aid evaporation with strong air movement In hot climates a powerful fan and tepid water are almost universally available, and it is usually possible soon to accelerate cerebral cooling with an ice bag, or even ice wrapped in a towel, applied to the head

I have no wish to decry the work of anyone who uses refrigerated water or iced baths, because I feel that in their experienced hands this form of treatment is both successful and safe To the average doctor, however, heatstroke is a comparatively uncommon emergency and treatment must be given at once with facilities readily available I can assure you that it is perfectly possible to treat successfully hyperpyrexia of any ætiology by sponging with tepid water and a strong air blast from a fan, even in conditions of high relative humidity and high ambient temperature

R.A F Institute of Pathology and
Tropical Medicine,
Halton Aylesbury Bucks R Mortimer

Sir,—Your leader is very valuable Hyperthermia (as we used to call it) will follow the treatment of patients with malaria, sandfly fever, enteric fever, and influenza in uncooled hospital wards Cardiac failure is uncommon in hyperthermia, except when the condition has persisted untreated for some hours

Servicemen have been known to report sick, with pyrexia, and been sent back to their quarters, and found hyperthermic and unconscious some hours later, in such cases cardiac failure is not uncommon and the response to the most enlightened treatment is disappointing

As you say, proper application of the principles of prevention, which are well known, should be everywhere applied, especially in Service communities, and devices for effective cooling should be at hand in all situations where heatstroke is known to occur I emphasised this in 1937 [1]

St Margaret's Hospital,
Epping Frank Marsh

SPONTANEOUS FRACTURE OF THE FIBULA

Sir,—Dr Hobbs (Oct 22) raises an interesting point when he states that in fatigue fractures of the fibula no adequate explanation of their occurrence has been given

These fractures occur in two main groups (1) the young and athletic and (2) the middle-aged and tired The case described clearly is of the second type Fatigue in bone may be compared in some respects to that in other materials such as metal When a metal column is subjected to repeated eccentric loadings, alternating tensile and compressive strains occur and eventually lead to a fatigue or stress fracture This also happens experimentally in bone Gaynor Evans [2] reported on subjecting a piece of fibula to repeated cyclical loadings at 5000 lb per square inch, and after 3,000,000 such loadings fatigue fractures occurred

In life, however, bone has a built-in capacity to repair by osteoblastic action and only when the stimuli are repeated sufficiently within the time taken to repair is a fatigue fracture liable to occur This period is likely to be prolonged in the middle-aged Even then, if aching causes the activity to cease, the early fracture may pass unrecognised

Windsor Roy Maudsley

POLIOVIRUS-NEUTRALISING ANTIBODIES IN STOOLS

Sir,—Dr Godtfredsen's letter of Aug 13 reported failure to demonstrate poliovirus-neutralising antibody in the stools of 13 convalescent individuals We appreciate being informed of these results and hope that she and others will not cease efforts to determine the nature of resistance of the human alimentary tract to poliovirus following infection with wild polioviruses or the feeding of attenuated living poliovirus vaccines Such alimentary resistance does not accompany Salk vaccination

Our communication [3] reported the demonstration of specific antibody in the stools of 13 children recovering from poliomyelitis Actually this represented only the positive results, the tests were performed in 93 convalescing patients and *only* 13 individuals were positive Once a given stool is demonstrated to contain type-specific poliovirus antibody, the observation can be repeated and appreciable loss of titre through storage and re-thawing has not been observed The serotype of antibody observed in our 13 positive children were 5 for type 1, 3 for type 2, 4 for type 3 One child's specimens neutralised types 1 and 2 When antibody was found in the stools the same type (and of course one or both remaining types) of antibody was found in the serum As we pointed out, the stool antibody when found was always *heterotypic* to the infecting virus, suggesting that those individuals' alimentary tracts had had previous exposure(s) to poliovirus

Deviations in Dr Godtfredsen's technique from ours include our use of a suspended-cell technique, which has advantages in demonstrating "low-avidity" antibody, and our use of 0 25 ml of the stools tested instead of 0 1 ml

---

[1] Guthrie J, McCraken, A V *Lancet*, 1960, i, 682

[1] British Encyclopædia of Medical Practice vol vi, p 396 London 1937

[2] Gaynor Evans, F Stress and Strain in Bone Springfield, Ill, 1957

[3] *Lancet* 1959, ii, 272

Whether the test details per se are important is uncertain, but more children may need testing our record of 13 of 93 individuals (± 14%) suggests this Failure to demonstrate in vitro neutralising antibody of the usual kind in the stools of the remaining 80 patients may be purely technical or may have fundamental explanations The age of patient, time of stool-collections after the current infection, previous alimentary contact with the other serotypes of poliovirus, the "secretor" status of the patient's alimentary tract, and other factors may influence the results

Ascertaining the modus by which the alimentary tract resists infection after experience with live virus but not following intramuscular vaccination is important from the epidemiological, clinical, and general biological points of view It is hoped that studies of this kind with varying approaches in technique will be conducted by as many workers as can interest themselves in this field

University of Louisville, Kentucky

ALEX J STEIGMAN
MURRAY M LIPTON

STERILISATION OF THE DIABETIC'S SYRINGE

SIR,—The recent correspondence on this subject recommends several methods to be safe and trouble-free

On the one hand, Dr Wauchope (Sept 10) doubted whether sterilisation was necessary and described her fortunate personal experience without any infections for many years But I fear that many insulin patients would have less high standards of cleanliness than hers and this is a very important point not mentioned in the previous correspondence How well I remember a young woman who, after five years of trouble-free injections, developed mysterious abscesses on both thighs The bath she received on admission to hospital for investigation stopped all further troubles, and she told me that she had moved to a house where there was no bath and this explained her abscesses

What do the insulin manufacturers say in their insulin packages? Nothing very definite. Most of them say that boiling in tap-water is desirable but as that is not always possible, advocate keeping the syringe and needles in spirit

The balance of the advice given by your correspondents is to favour spirit alone, although the initiator of the correspondence, Dr Stephen Carter, boils his syringe four times a year and uses no spirit

London, W 1

R D LAWRENCE

SUICIDE

SIR,—Reading Dr Stewart's article of Oct 22 it is difficult not to feel compassion for many of the 85 suicides in his series of 122 who had been suffering from various painful or disabling diseases

Is it not time that the coroner's court formulæ, "while the balance of his mind was disturbed" or "while of unsound mind", should be discarded in the absence of clear evidence of mental disturbance prior to suicide? Some people who commit suicide to terminate a life that has become a life-sentence of intractable pain are taking a step that seems sensible albeit desperate

As you report last week (p 976), a Bill to provide that suicide and attempted suicide should no longer be criminal offences has been drawn up and approved by the Criminal Law Revision Committee So need we penalise the suicide by casting an unmerited slur on his sanity just because he has committed suicide?

With regard to attempted suicide, Prof E Stengel[1] has for a long time taught that one of its main motivations is the appeal of a desperate individual for help from his fellow-men Unless the family or friends of the attempted suicide are alerted to his dangerous dilemma by the suicidal attempt, the only practical step likely to prevent a second, possibly successful, attempt would seem to be bringing him before the courts and placing him on probation on condition that he receives necessary psychiatric treatment It is to be hoped that this potentially lifesaving course will not be made more difficult if the new Bill becomes law

London, W 1

F R C CASSON

THE NATURE OF ESSENTIAL HYPERTENSION

SIR,—I really must take exception to the data which Dr Marshall (Oct 22) alleges add to the solution of this problem, and the conclusions he draws from these data

My old chief, Sir Thomas Lewis, would not allow readings of blood-pressure taken by nurses to appear in scientific publications The estimations which Dr Marshall uses were made by "specially trained nurses at hourly intervals during one day a patient spent in hospital" They were made to the nearest even number Dr Marshall states that digit preference can be excluded because the nurses had no incentive Nor had those employed by Boe, Humerfelt, and Wedervang[1] in their measurements made on 67,976 inhabitants of Bergen Yet digit preference was more marked than in any other series I know 85% of systolic readings (series I) ended with 0 and only 15% with 5 For diastolic readings the percentages were 87 and 13 respectively Diastolic pressures had a bimodal distribution in the second but not in the first sample This bimodality was most probably due to a change in the team of nurses making the measurements There is no analysis in Dr Marshall's paper of the distribution of readings, nor any evidence that steps were taken to assess how accurate the readings were

As disturbing is his statement "Moreover, the blood-pressure figures used in this study were means of six readings taken under constant conditions" To those who work in the field of science, "constant conditions" has a clear implication, and is a state, in fact, very rarely achieved Dr Marshall's 134 patients "attended hospital for one day during which they rested on a bed in the supine position Their blood-pressure was recorded hourly for six hours by specially trained nurses, who read the sphygmomanometer to the nearest even number" One could perhaps imagine that from 10 to 4 the patients lay on a bed in a side-ward and were visited only by the nurses But this was not so "During the one day in hospital the patients had a physical examination, chemical and microscopic examinations of the urine, estimation of the blood-urea and blood-cholesterol, an electrocardiogram, and a radiographic examination of the heart and skull"

Dr Marshall's averages of six values, each to the nearest even number, will give him a series of integers which perhaps he might take to one place of decimals As set out they are arranged in groups at intervals of 8 or 12 mm Hg He does not say how this grouping has been done And yet it is vital to the conclusion the reader is invited to accept

However, the worst feature of Dr Marshall's paper is his evidence for bimodality A protest has been made before against interpreting irregularities in frequency distribution curves as bimodality, especially when the numbers are small Fortunately Dr Marshall has now brought this practice to what must be the all-time low

---

[1] *Lancet* 1952, i, 1059

[1] Boe J, Humerfelt S, Wedervang, F *Acta med scand* 1957 suppl 321

He says " The systolic pressures of patients over 60 years had a bimodal distribution irrespective of whether their parents died below or above the age of 65 (fig 5)" Fig 5 shows the frequency distribution curve of 26 patients whose parents had died under the age of 65 Here are data taken from fig 5 for this group

Systolic B P	*Frequency %*	*Actual number*
108	4	1
120	12	3
132	4	1
144	8	2
156	12	3
168	24	6
180	16	4
192	8	2
204	12	3
Total	100	25

The contention evidently is that a series 1 3 1 2 3 demonstrates bimodality

Finally, supposing that an analysis of patients between the ages of 31 and 70 showed that there were essentially two populations as regards blood-pressure—and has this not been shown by Dr Marshall ?—could this be accepted as evidence that essential hypertension is the manifestation of a single gene ? For Dr Marshall states " It seems likely that the appearance of a group with raised blood-pressure is caused by a hereditary factor—probably, as Platt suggested, due to a mendelian dominant " It should be clearly stated that cerebral vascular disease consists of at least three entities occlusion of the arteries in the neck, of those within the cranium, and cerebral hæmorrhage There is a strong suspicion that the last is more closely associated with grossly raised pressure than the first of these Dr Marshall says that these patients had " what was judged on clinical grounds to have been a non-embolic cerebral infarction ", but, as previously reported,[2] his trial of anticoagulant treatment had to be stopped because of the incidence of fatal cerebrovascular accidents due to cerebral hæmorrhage in the treated group Had he indeed demonstrated two populations in cases of cerebrovascular disease this would have no bearing whatsoever on whether essential hypertension is or is not the manifestation of a single gene

Oxford G W PICKERING

SIR,—Before some of your readers should be tempted to interpret the results found by Dr Marshall as cogent evidence in the conflict of views on the nature of essential hypertension, could we have the answers to some simple questions ?

(1) We are told that the subjects studied had all previously had what was judged to have been a non-embolic cerebral infarction In what ways were these survivors thought to be representative of all people suffering cerebral infarction, how were the subjects selected, and why were there 91 males and only 43 females when mortality-rates from vascular lesions involving the central nervous system show no gross sex difference

(2) Having demonstrated such very different frequency distributions of arterial pressure in the two sexes as those shown in fig 1 (*b*) and (*c*), what is the justification for combining the two sexes in all subsequent analyses ?

(3) In analysing blood-pressure data for subjects aged 31-70 is it reasonable to use only two age-groups, above and below 60, when the evidence derived from the general population shows arterial pressure to be very sensitive to age ?

(4) The grouping of pressure into units of 12 mm Hg for systolic and 8 mm for diastolic pressure is unusual Could this have influenced the shape of the published curves ?

The type of study carried out by Dr Marshall could be repeated in many hospitals in the country but have little value unless confirmed in less highly s populations Before we are confused by more an bimodal curves, may I make a plea, Sir, that should publish their data in a form that enables int readers to evaluate them and allows comparison wit published work, and particularly with the careful Platt and Pickering Pictures alone are unsatisfac

Llandough Hospital,
Penarth, Glamorgan W E Mi

SIR,—There seems to be a growing and unfo tendency, especially in communications on hypert to argue from diagrams The latest example is th of Dr Marshall, who relies upon them entirely an no figures at all It must be admitted, however, t sin is a minor one, for as his numbers are very sm corresponding frequencies can be reconstructe almost complete accuracy from his curves shown centages Nevertheless, one would like to have th data in less coarsely grouped form And, incide how can pressures measured to the nearest even n be added so as to yield the series of figures sh group centres in all the diagrams ?

The following opening paragraph has appea chapter II in all successive editions of R A F *Statistical Methods for Research Workers*, right back first edition of thirty-five years ago

> " The preliminary examination of most data is facilitated use of diagrams Diagrams prove nothing, but bring outs features readily to the eye, they are therefore no substitute critical tests as may be applied to the data, but are val suggesting such tests, and in explaining the conclusions upon them "

The current discussion on the nature of es hypertension will be greatly helped if these wise wo remembered, and if authors give as much of thei data as possible, apply suitable tests, and in par explain just what they have done, desiderata str lacking in some recent papers The curves can the their proper purpose of illustration and light relief

MODERN CLINICAL BIOCHEMISTRY

R,—I would not put the clock back 50 years as Dr dry forbids (Oct 29), but 113 years and quote from how's paper, Standpoints in Scientific Medicine can learn much from chemistry, but we will have to ve for ourselves the privilege of applying its findings " how was familiar with the appreciable number who Dr Hendry's outlook in his 1855 paper on Cellular ology he writes " The condescension with which the onents of chemical and physical viewpoints—even who have only a very imperfect understanding of oscopic anatomy—look down on morphology is known "

om my student days I have had the highest regard for d we receive from competent biochemists if they their right place in the team they are invaluable I ngly dislike splitting the pathology department into or more watertight compartments Whenever I look n my microscope problems in bacteriology, hæmato- , or biochemistry arise, with the aid of one or other mber of my team these are followed to the advantage of clinician and patient Our biochemist regularly draws attention to problems which should be followed in er departments Without a medical training very few chemists are safe in advising on the meaning of many their findings A good example of the interdependence the four departments of the pathological laboratory was man of 23 admitted to one of our surgical wards in a ate of diabetic coma When the biochemist told me of s very high blood-sugar I at once asked why he was in a urgical ward it was because he had had a bladder-neck peration for enuresis there three months before I discovered that he was not then a diabetic, so we at once amined his blood for severity of infection (if any), and is urine for pus and organisms The real diagnosis was uickly established as pyonephrosis, and unfortunately roved at necropsy To me all sections of the laboratory e equally important in general Who is the most important departmental head varies with the case, for the young an just mentioned I would say it was the hæmatologist ecause he said clearly death from infection is inevitable the absence of successful treatment

The question of who is the most important, the pathogist or one or other of the technical heads of departments, an absurd one It is well answered by Leo Tolstoy in s short story Three Questions written in 1903 (in *wenty-Three Tales*) I hope Dr Hendry and others who ink like him will read this The practical point is that pathologist is usually the only one who can bring all ctions of the laboratory to the aid of the clinician, he ove all others can cheat death when he calls too soon e greatest emotional satisfaction is to be found in neral practice, the greatest intellectual satisfaction in the ological department The former is warm, the latter o often cold, that is why many of us feel like Dr Hendry t times If this emotional satisfaction is wanted, do not ecome a physician or surgeon as Professor Cappell ossibly suggests, for they occupy a half-way position, btain a medical qualification and enter general practice

r Hendry may be shocked to know that to me the iochemist ranks equally with the senior technician in harge of hæmatology, bacteriology, and histology I do ot know which is the most important until I know the blem If the training of a biochemist is more difficult, d all will not agree with this, they should be paid re—as they are This makes a psychological barrier een them and the technical heads of the other departments which a wise biochemist will do all in his power to destroy

Biochemists are not at the crossroads looking four ways at once at the moment they are looking on the way out only If that happens it will be a tragedy We do not have far to look to see non-medical biochemists who are invaluable in the practice of medicine, they are professors or of that calibre This is taken to mean, by some, that all we need to do to obtain a good biochemical service is to appoint a good chemist in charge of it and then keep away This is nonsense My biochemistry department owes a lot to men with medical qualifications, these are ideal but in short supply Even Dr Hendry might allow that the greatest clinical biochemist of all time was the medically qualified Paul Ehrlich

How should the pathological services of the future be planned? Division into a number of watertight compartments is an evil which may be necessary in places The right thing seems to me a large general clinical laboratory where a problem in a patient is studied, not just a test performed This should be backed by small reference laboratories in the same building Most of the routine biochemistry should be done in the clinical laboratory—including the blood sugars and ureas for which Dr Hendry has such contempt, though if I could have only two biochemical investigations I would pick these

How should junior and senior members of the medical profession use the pathological services? I give two answers to this Because so many tests are needed the pathologist can no longer attend to all Many are straightforward and the patient progresses well, these cases justify a request for a given test Many patients are diagnostic problems or are unsatisfactory If a patient is, say, unsatisfactory after an abdominal operation I like the surgeon to tell me what he did and invite our help At the moment many are obsessed with biochemistry to the exclusion of the other branches The correct use of all departments will invariably say peritonitis, ileus, both or neither We want to know the process, not some minute detail of it When we begin our training with the microscope we use the highest magnification we can get, and feel that if we could only obtain something larger we would know everything As we become more experienced we use the lowest magnification so that we can see the process This earns us scorn from the most junior my son, when a dental student, assured me that I only guessed at such a low magnification I fancy that many, who should know better, feel that in biochemistry they have something of higher magnification than the electron microscope Perhaps they have, but the sap in a leaf tells you little about the plant and less about the forest.

May biochemists read Leo Tolstoy and remain our honoured colleagues May I be permitted to salute Professor Cappell's masterly survey

Derbyshire Royal Infirmary,
Derby

G R OSBORN

SIR,—There is an element of truth in Dr Hendry's statements about the interrelationship of " pathologist " and biochemists, but surely many will think he overstates his case, and confuses any serious analysis of the position, both by his caustic wit and blatant misuse of the names of the reactants It is patently absurd to imply that each large hospital should have an autonomous biochemistry department such a separist movement would be harmful to the patient and the clinician, and more particularly to

the biochemist himself What is clearly needed is a greater integration of the laboratory services, both within their own house and within the framework of the hospital as a whole No hospital worker, be he physician, surgeon, histologist, or biochemist, can go it alone, even if the latter thinks he can do it all himself It is, of course, platitudinous to say there is no place for the enthusiastic amateur in this modern scientific work, each specialist must overtly be trained as such, but he would be a fool indeed to suppose he alone has something to offer the patient, whatever the latter's disease

Pathology is the study of disease however Dr Hendry may interpret biochemistry to himself, in clinical practice it is the application of chemistry to the study of human disease, and it must follow that even he is to some extent a pathologist I personally would like the terms pathologist and pathology laboratory, as currently used, to be discontinued, in hospitals at least Instead, the terms bacteriologist, biochemist, biophysicist, hæmatologist, histologist, or virologist could be used according to taste each worker should have an individual laboratory, but all should be contiguous and in one central building, so having common meeting and stamping grounds Medicine and pathology have both suffered enough enthusiastic divisionists already without further chemical schizists

J A Wakis Miller

VIRUS INFECTIONS DURING PREGNANCY

Sir,—I read your leader of Oct 8 with much interest, because it fell to me to review this topic at the First International Conference on Congenital Malformations held in London in July, 1960

May I take this opportunity to encourage those readers who may be continuing to investigate the outcome of rubella in pregnancy to arrange for the assistance of a laboratory where virus diagnostic tests can be performed?

Although the rubella virus has not yet been isolated—and we have had many negative results in Toronto—the Echo viruses that may cause a similar clinical syndrome can be readily grown in tissue culture

Work done on the Echo viruses in Canada and many other parts of the world has convinced me that a diagnosis of "rubella" or "german measles" obtained from a patient must be considered unreliable Even a physician may mistake infection with an Echo virus (especially type 9) for rubella In differentiation, it is important to note the short incubation period of Echo infections (3–5 days)

Epidemiological studies such as those commented on in your editorial have produced substantial results Such studies may, however, prove even more rewarding in th future when epidemiological techniques are correl with the more precise laboratory techniques of th modern medical virologist

HAZARDS OF BARIUM-SULPHATE ENEMA

Sir,—Your annotation of Oct 8 refers to barium sulphate pulmonary embolism The following case may therefore be of interest as a record of a further hazard in relation to this common diagnostic procedure

A fit man of 70 was referred from the outpatient department for barium enema He complained of mucous diarrhœa Technically the enema was uneventful On walking from the X-ray table he complained of sudden severe abdominal pain and collapsed to the floor The radiologist reported that he was unconscious for some seconds He was transferred immediately to a general medical ward

When examined he was conscious, complaining of generalised abdominal pain and mentioned a transient sharp left-sided chest pain No peripheral pulses were detectable, blood pressure was unrecordable and the jugular venous pressure was raised It was then observed that a striking generalised erythema was developing it reached a maximum some 45 minutes after completion of the enema, and faded gradually over the next 6 hours

Immediate resuscitation was symptomatic, using oxygen, *morphine, intravenous pressor agents, and intramuscular* promethazine Chest X-ray, plain X-ray of the abdomen, electrocardiogram, serum-transaminases, and urinary 5-hydroxyindole-acetic acid were all subsequently shown to be normal The barium enema showed a few diverticula in the sigmoid colon but no other abnormality The patient made an uneventful recovery and was discharged 10 days later The cause of his abdominal pain remains obscure

In view of the negative findings and the clinical picture, this man may have had an acute hypersensitivity reaction The barium enema was made up in 1% tannic acid and was preceded by colonic irrigation with tap-water followed by 'Veripaque' enema A similar investigation 4 months previously with the same preparation was entirely uneventful Skin tests using 1% tannic acid were negative

Fatal collapse due to proven barium-sulphate pulmonary embolism has now been reported [1] A second case in which this diagnosis seems highly probable, although necropsy was not allowed, has recently been recorded [2] Acute "water intoxication" in the preparation of children for barium enema is now a well-recognised and sometimes fatal hazard [3–5] But the condition I have described does not seem to have been recorded previously

Over 1000 barium enemas are performed annually in this hospital, no member of the staff of the department of radiology has seen or heard of a similar case Although,

ACUTE COPPER POISONING

SIR,—The paper by Professor Semple and his colleagues (Sept 24) is very timely, especially because the possibility of toxic hazards from copper heating vessels does not seem to be generally appreciated [1]

It may be of interest to recall that Dr Harold Jacobziner, assistant commissioner of the New York City Department of Health, commented last year on the toxic hazards of copper as well as other metals in hot tap-water drawn from corroded pipes lined by these metals [2] He said that he had in his files " the report of an investigation of a case where several persons became ill due to excessive copper in water drawn from the bottom of a hot water tank " Jacobziner was commenting on a paper [3] which had recommended the use of hot tap-water in the preparation of infant feeds

GEORGE X TRIMBLE

ORAL TREATMENT OF PERNICIOUS ANÆMIA WITH LOW DOSES OF H P P /1

SIR,—Dr Varadi (Oct 15) must realise how increasingly difficult it has now become for us to assess the significance of his findings, faced as we are with three differing descriptions of the treatment given, and the responses obtained, from the same ten cases It is also a matter of some surprise to find that he classifies a case as " relapsed " (Sept 17) when, in fact, the patient did not suffer a deterioration in the blood-picture at all, but merely a fall in the serum-B_{12} level when the daily dose was reduced from 300 µg to 100 µg of B_{12}

Finally, it is a little disappointing that Dr Varadi has still declined to explain the scientific basis of his interpretation of serum-B_{12} levels, when applied to this particular form of therapy We do not doubt that the estimation may be of some value in confirming a diagnosis in the untreated case of pernicious anæmia, but we would like to know what evidence he has for the conclusion in the penultimate paragraph of his letter of Sept 17, that serum-B_{12} levels also reflect the degree of intestinal absorption, *on this particular form of therapy*

St Helens Hospital

F S MOONEY
J G HEATHCOTE

SIR,—Like Dr Varadi and Mr Elwis (Sept 17) I have been investigating the serum-vitamin-B_{12} levels of patients with pernicious anæmia in relapse who have been treated with vitamin-B_{12}/peptide (' Distivit ')

In 8 such patients receiving 200 µg daily or less, followed for periods of three to eighteen months, the serum-B_{12} concentration rose above 200 µµg per ml in 1 case only A further 2 patients given 500 µg daily for a period of eighteen months maintained serum levels around 400 µµg per ml These results are broadly similar to those previously reported [4] using oral crystalline vitamin B_{12} With the exception of 1 patient receiving 100 µg daily, all these cases reached and maintained normal values of hæmoglobin, red-cell counts, and packed-cell volumes, so Dr Mooney and Dr Heathcote (Oct 1) could again, on this evidence alone, question the scientific basis for using serum-vitamin-B_{12} levels as proof of adequate dosage I submit however that, as a general concept of rational therapy, it is desirable to give a sufficient amount of the vitamin to maintain the serum level near the average normal mean—that is, about 400 µµg per ml It therefore seems necessary, if oral treatment for pernicious anæmia is considered desirable for a particular patient, that over 200 µg daily should be administered, whether the vitamin B_{12} is in a crystalline form or a peptide complex

BROADER MEDICAL TEACHING

SIR,—May I comment on your interesting annotation Broader Medical Teaching (Oct 22) ?

On Oct 23, 500 general practitioners attended our third *Medical World* Conference One of the subjects was " Training for General Practice " From the discussion, several attitudes became apparent

(*a*) The G P s agreed unanimously that their medical-school training had not fitted them for their work, (*b*) that, with few exceptions, hospital doctors who had trained them had little knowledge or understanding of the problems facing the G P , (*c*) that, despite a growing awareness of these deficiencies in training, the situation has not improved of recent years

In a laudable attempt to correct an unbalanced system of training, some universities and the College of General Practitioners have introduced schemes to allow medical students to see something of general practice during their training Apart from local schemes which allow students to spend a few weeks with selected G P s, there are the Edinburgh and Manchester University schemes On a more ambitious scale the Inverness Regional Hospital Board is providing rotating internships, which include attachment to G P s, and the Wessex scheme financed by one of the Nuffield Trusts is seeking to provide young G P s with a chance to see something of all three branches of the Service

No-one would wish to minimise these efforts Yet surely they leave the main problem unsolved The hospital teacher who will continue to form the minds of new generations of students is still out of touch with the problem of general practice How can this be otherwise when the career structure in the hospital field demands that the young trainee consultant should unremittingly follow the narrow lines of his specialty ?

I suggested at our conference that the problem could be partly solved if every future teacher in the hospital service had to spend a period in general practice—a proposal which was warmly welcomed The time to do so would be between the registrar and senior-registrar appointments—i e , before the young specialist sets his foot on the ladder from which he dare not fall off If the time spent in general practice were made a condition of appointment to a senior-registrar post, no-one would gain an unfair advantage

Unlike the G P trainees, these young aspiring specialists would not have to be taught general practice by selected good G P s Their need is to see the realities of practice in all its forms They could be attached to four different types of practice for six weeks each, and could learn quickly some of the problems facing the industrial, semi-urban, rural, and seaside G P In all, this would occupy only six months of their working lives, yet it could have a profound and beneficial effect on the future training of the medical student—and, indeed, on British medicine

therefore, a most unusual event, its seriousness seems to warrant more general recognition We are hoping to do further studies in an attempt to determine the nature and cause of this reaction It would be interesting, meanwhile, to hear of any similar incident

I should like to thank Dr G D Hadley for his advice and permission to publish this case

ACUTE COPPER POISONING

SIR,—The paper by Professor Semple and his colleagues (Sept 24) is very timely, especially because the possibility of toxic hazards from copper heating vessels does not seem to be generally appreciated [1]

It may be of interest to recall that Dr Harold Jacobziner, assistant commissioner of the New York City Department of Health commented last year on the toxic hazards of copper as well as other metals in hot tap-water drawn from corroded pipes lined by these metals [2] He said that he had in his files "the report of an investigation of a case where several persons became ill due to excessive copper in water drawn from the bottom of a hot water tank" Jacobziner was commenting on a paper [3] which had recommended the use of hot tap-water in the preparation of infant feeds

Memorial Hospital of Long Beach
Long Beach, California

GEORGE X TRIMBLE

ORAL TREATMENT OF PERNICIOUS ANÆMIA WITH LOW DOSES OF H.P P /1

SIR,—Dr Varadi (Oct. 15) must realise how increasingly difficult it has now become for us to assess the significance of his findings, faced as we are with three differing descriptions of the treatment given, and the responses obtained, from the same ten cases It is also a matter of some surprise to find that he classifies a case as "relapsed" (Sept. 17) when, in fact, the patient did not suffer a deterioration in the blood-picture at all, but merely a fall in the serum-B_{12} level when the daily dose was reduced from 300 μg to 100 μg of B_{12}

Finally, it is a little disappointing that Dr Varadi has still declined to explain the scientific basis of his interpretation of serum-B_{12} levels, when applied to this particular form of therapy We do not doubt that the estimation may be of some value in confirming a diagnosis in the untreated case of pernicious anæmia, but we would like to know what evidence he has for the conclusion in the penultimate paragraph of his letter of Sept 17, that serum-B_{12} levels also reflect the degree of intestinal absorption, *on this particular form of therapy*

St. Helens Hospital

F S MOONEY
J G HEATHCOTE

SIR,—Like Dr Varadi and Mr Elwis (Sept. 17) I have been investigating the serum-vitamin-B_{12} levels of patients with pernicious anæmia in relapse who have been treated with vitamin-B_{12}/peptide ('Distivit')

In 8 such patients receiving 200 μg daily or less, followed for periods of three to eighteen months, the serum-B_{12} concentration rose above 200 μμg per ml in 1 case only A further 2 patients given 500 μg daily for a period of eighteen months maintained serum levels around 400 μμg per ml These results are broadly similar to those previously reported [4] using oral crystalline vitamin B_1 With the exception of 1 patient receiving 100 μg daily, all these cases reached and maintained normal values of hæmoglobin, red-cell counts and packed-cell volumes, so Dr Mooney and Dr Heathcote (Oct 1) could again, on this evidence alone, question the scientific basis for using serum-vitamin-$B_{1\_}$ levels as proof of adequate dosage I submit however that as a general concept of rational therapy, it is desirable to give a sufficient amount of the vitamin to maintain the serum level near the average normal mean—that is, about 400 μμg per ml It therefore seems necessary, if oral treatment for pernicious anæmia is considered desirable for a particular patient, that over 200 μg daily should be administered, whether the vitamin B_{1}. is in a crystalline form or a peptide complex

BROADER MEDICAL TEACHING

SIR,—May I comment on your interesting annotation Broader Medical Teaching (Oct 22)?

On Oct 23, 500 general practitioners attended our third *Medical World* Conference One of the subjects was ' Training for General Practice" From the discussion several attitudes became apparent

(*a*) The G P s agreed unanimously that their medical-school training had not fitted them for their work, (*c*) that, with few exceptions hospital doctors who had trained them had little knowledge or understanding of the problems facing the G P , (*c*) that, despite a growing awareness of these deficiencies in training, the situation has not improved of recent years

In a laudable attempt to correct an unbalanced system of training, some universities and the College of General Practitioners have introduced schemes to allow medical students to see something of general practice during their training Apart from local schemes which allow students to spend a few weeks with selected G P s, there are the Edinburgh and Manchester University schemes On a more ambitious scale the Inverness Regional Hospital Board is providing rotating internships, which include attachment to G P s, and the Wessex scheme financed by one of the Nuffield Trusts is seeking to provide young G P s with a chance to see something of all three branches of the Service.

No-one would wish to minimise these efforts Yet surely they leave the main problem unsolved The hospital teacher who will continue to form the minds of new generations of students is still out of touch with the problem of general practice How can this be otherwise when the career structure in the hospital field demands that the young trainee consultant should unremittingly follow the narrow lines of his specialty?

I suggested at our conference that the problem could be partly solved if every future teacher in the hospital service had to spend a period in general practice—a proposal which was warmly welcomed The time to do so would be between the registrar and senior-registrar appointments—i e , before the young specialist sets his foot on the ladder from which he dare not fall off If the time spent in general practice were made a condition of appointment to a senior-registrar post, no-one would gain an unfair advantage

Unlike the G P trainees, these young aspiring specialists would not have to be taught general practice by selected good G.P s Their need is to see the realities of practice in all its forms They could be attached to four different types of practice for six weeks each, and could learn quickly some of the problems facing the industrial, semi-urban, rural, and seaside G P In all, this would occupy only six months of their working lives, yet it could have a profound and beneficial effect on the future training of the medical student—and indeed, on British medicine

Obituary

ALAN BROWN

M D Toronto, F R C P (C), F R C P

Dr Alan Brown was one of the pioneers of pædiatrics in Canada For over thirty years he was physician-in-chief to the Hospital for Sick Children in Toronto, and when a chair of pædiatrics was set up in the University of Toronto in 1935 he was appointed the first professor He died on Sept 7 at the age of 73

He qualified from the University of Toronto in 1909, and spent five years as a resident physician in the Babies' Hospital (Columbia University), New York After further postgraduate study in Germany, Austria, Denmark, and Britain, he was appointed to the medical staff of the Hospital for Sick Children in Toronto in 1915 Four years later he became its physician-in-chief Under his direction the hospital became a centre for the training of medical undergraduates, pædiatricians, and nurses In 1919 he was appointed an associate professor of medicine in the university, and in 1935 head of the newly created department of pædiatrics He served for many years as consultant to the local, provincial, and national departments of health, as well as to three other Toronto hospitals and the former Infants' Home He was a founder and past president of the Canadian Pædiatric Society He retired from his hospital appointments and his chair in 1951

As a writer and a visitor he was well known on both sides of the Atlantic His book on *The Normal Child*, first published in 1926, is now in its fifth edition, and with Dr F F Tisdall he published a useful survey of *Common Procedures in the Practice of Pædiatrics* He gave many clinical lectures, and his colleagues in this country will recall his Ingleby lectures in 1948 on the scientific construction of the normal child's diet He was a corresponding member of the British Pædiatric Society and was elected F R C P in 1940

E C R writes

"Alan Brown crusaded vigorously for many improvements in the care of infants and children, including the proper formulation and sterilisation of infant feedings, the compulsory pasteurisation of milk, and the universal use of diphtheria toxoid and other well-established immunisation procedures Soon after he became physician-in-chief, he organised a small research laboratory at the hospital which, with his support and encouragement, has grown greatly with the years in both size and reputation Canadian pædiatrics in general and the Hospital for Sick Children in particular owe a great deal to his vision, unusual energy, and outstanding organising ability "

Dr Brown married Miss Constance Hobbs in 1914 She survives him with their two daughters

CLAUDE WILFRED ALFRED KIMBELL

M B N Z , F R C O G , F R C S E

Mr Claude Kimbell, gynæcological surgeon to the Samaritan Hospital for Women, London, died on Oct 26 at the age of 55

A New Zealander by birth, he was educated at Wellington College and the University of Otago, where he graduated M B in 1930 The following year he came to this country for postgraduate studies, and in 1935 he took the F R C S E and in 1937 the M R C O G During the late war he served in the R.A M C with the rank of major He remained behind at Dunkirk to look after the wounded and spent the rest of the war as a prisoner in Germany Afterwards he returned to practise obstetrics and gynæcology in London and was appointed to the staff of the Samaritan Hospital and the City of London Maternity Hospital He was elected F R C O G in 1953 He was a founder member of the Gynæcological Travellers' Club

C M G , one of his colleagues at the Samaritan Hospital, writes

"Claude Kimbell was a sick man for many years, but because of his courage and interest in life he continued with his work In the Samaritan Hospital he was loved by everyone he worked with in the outpatient department, wards, and theatre. An excellent surgeon, he was interested in the total human and always concerned with the psychological implications of a case He was a perfectionist and ever ready to sacrifice himself for his patients and friends From his experience as a prisoner-of war he had learned not bitterness but a deep sympathy and understanding of his fellows "

J H , who first met Kimbell twenty-five years ago on visits to Liverpool when Kimbell stayed with his fellow New Zealander, the late Charles Marshall, came to admire "his many qualities as friend and surgeon" He relates

"Knowing that his health was failing Kimbell lately made a trip to Canada as a ship's surgeon to see his married daughter and grandchildren In a Newfoundland hospital he found a sailor who had been seriously injured four months previously No one would take the responsibility to send the sailor back to England and his family It was typical of Claude Kimbell that he organised a passage home on his own ship for this injured man, and on arrival in Liverpool with great energy arranged for him to be sent home to his family

"As a surgeon Kimbell was meticulous in detail and deft in technique As a man I can sum him up in four words—modest, honest, generous, and always considerate of others "

Public Health

The Registrar General's Commentary

In his commentary on the vital statistics for 1958 the Registrar General[1] notes that the birth-rate of 16 4 per 1000 was the highest recorded since 1949 There were 740,715 live births, the largest number since 1948 The birth-rate per 1000 women aged 15–44 was 82 1 in 1958, which was above the level of the early 1920s and 32% higher than the 1938 rate The birth-rate was highest in Merseyside and lowest in Greater London

Population —The annual rate of increase amounted to about 0 5% of the population, a little less than the average rate of population increase for Northern and Western Europe, and only a third of the rate of increase in Asia The estimated total population at mid-1958 was 45,244,000 (21,877,000 were males and 23,367,000 females)

Marriages —In the 15–24 age-group, the proportion married has more than doubled since 1931 for both men and women Although total marriages were 7000 less than in 1957, the rates continued to rise slightly at the younger ages In 1954, 6 9% of bridegrooms and 28 6% of brides were minors, the corresponding figures for 1958 were 10 7% of bridegrooms and 35% of brides

Deaths —The crude death-rate—11 7 per 1000 persons of all ages—showed little change With allowance for population age-changes, the average reduction in mortality has been 60% in the past fifty years, and 40% in the past twenty-five years Between 15 and 24 years, the death-rate for males is more than double that for females, in this age-group seven times as many men as women die from accidents

Infant mortality —This continued to decrease deaths of children under 1 year numbered 22 5 per 1000 births in 1958, the lowest rate recorded till then Infant mortality as a whole has declined by two-thirds since 1928

Tuberculosis —There were 4480 deaths in 1958, compared with 19,797 in 1949 In the same time, annual notifications have declined from over 50,000 to 30,000

---

[1] Registrar General's Statistical Review of England and Wales, 1958 Part III, Commentary H.M Stationery Office *Pp* 222 *13s*

Accidental and violent deaths.—These have increased progressively, the totals being 18,513 in 1949 and 22,456 in 1958. The increase is due mostly to increases in motor-vehicle accidents, accidental gas-poisoning, falls, and, in women only, suicide. The death-rate among men in the 15–24 age-group from motor-vehicle accidents increased from 26 per 100,000 population in 1954 to 35 in 1958. Accidental deaths attributed to barbiturate poisoning increased from 77 in 1949 to 205 in 1958, and to domestic gas from 421 to 870.

The September Quarter

In England and Wales in the September quarter, 1960, there were 197,572 live births, 3873 stillbirths, and 112,379 deaths.[1] The birth-rate (17.2 per 1000 population) was the highest for a September quarter since 1948, when the corresponding rate was 17.5. The stillbirth-rate was low—19.2 per 1000 live and still births.

Parliament

Professions Supplementary to Medicine Bill

THIS Bill received the Royal Assent on Oct. 27. Its provisions will not come into operation until they are brought into force by Orders in Council.

QUESTION TIME

Hospital Casualty Services

Earl WINTERTON asked the Government whether, in view of the criticisms made by an unofficial committee of the methods for dealing with casualty cases in National Health Service hospitals and of other evidence to the same effect, they would appoint a committee of inquiry.—Lord ST. OSWALD replied: My Lords, the Standing Medical Advisory Committee of the Central Health Services Council appointed, earlier this year, a subcommittee, under the chairmanship of Sir Harry Platt, to consider the organisation of hospital casualty and accident services and to make recommendations regarding their future development. The Scottish Health Services Council has set up a similar committee. I have no doubt that these committees will consider the recommendations made in the study, based on 20 casualty departments, which was recently published for the Nuffield Provincial Hospitals Trust.

Lord STONHAM: Is the noble Lord aware that, at the instance of the Minister, every regional board has been considering this problem, that they are proposing to concentrate major casualty centres in the hospitals in each group, but that what is needed is more money to equip, expand, and provide more casualty centres? And can he say whether that will be forthcoming?—Lord ST. OSWALD: I think that any decisions of that nature must naturally rest upon the finding of this subcommittee, which has been set up specifically for the purpose of discovering what the facts are, and of suggesting remedies.

Means Test for State Scholarships

Mrs. EIRENE WHITE asked the Minister of Education what decision had been reached on the recommendations of the Anderson Committee on parental means tests for university students.—Sir DAVID ECCLES replied: I shall very shortly announce a radical revision of the present means test, to be brought in by the autumn of 1961. This is without prejudice to the abolition of the means test if that, on full examination, should turn out to be required.

Smokeless Zones

On Oct. 1 there were 296 smokeless zones or smoke-control orders in operation in England and Wales, covering 255,974 premises, and 98 more smoke-control orders, covering 123,219 premises, have been confirmed but were not in operation. Some 1270 local authorities have not made smoke control orders, but most of these do not have a major problem of domestic smoke pollution.

Notes and News

WORLD HEALTH ORGANISATION

THE Director-General of W.H.O., Dr. M. G. Candau, and the retiring senior W.H.O. representative in the Congo, Dr. J. S. MacKenzie Pollock, have both reported on the medical situation there.

In July W.H.O. responded to a request by the Security Council, and within a week 28 staff members had been sent to the Congo. 28 medical teams provided by 25 national Red Cross societies answered a joint appeal by the League of Red Cross Societies and the International Committee of the Red Cross. These teams were initially to stay three months. Some countries offered additional assistance, and soon hospitals, not only in the cities, but in the country as well, were able to function again.

At each provincial capital, except that of Katanga, there is a W.H.O. group, consisting of a public-health adviser, a public-health engineer, and a mobile epidemiological team. These mobile teams have already begun to organise vaccination campaigns against smallpox, typhoid fever, yellow fever, and plague. To deal with these diseases and the other major health hazards—malaria, filariasis, leprosy, and tuberculosis—many staff members are being recruited. They will be paid out of the U.N. Congo fund and placed at the disposal of the Congo Government. The main need is to staff the district services with doctors who will superintend the hospitals and organise preventive health services. 130 health personnel are being recruited now, and this number will soon be increased to about 500. The Red Cross teams have been asked to remain for six months, or longer if possible.

The long-term problems can be solved only by training Congolese doctors. There are none at present, and the local university, Lovanium, will graduate only 2 in 1961, and not more than 19 in all by 1965. Dr. Candau considers that the 1959 situation cannot be regained in less than twelve to fifteen years. But an encouraging start has been made. W.H.O. is providing 13 additional teaching staff, including the first professor of public health, which has enabled Lovanium University to increase its medical-student intake to 40. The three schools for "medical assistants" will finish the six-year training of the present students and then close. All students after that will complete the full medical course at Lovanium University. 74 "medical assistants" are at present helping to provide essential health services.

Meanwhile 60 "medical assistants" have been awarded W.H.O. fellowships and have left for French medical schools to qualify as doctors after special two-year or three-year courses. 7 students with no previous training have been awarded fellowships for a full medical course in France or Switzerland.

Dr. A. Bellerive (Haiti) succeeds Dr. McKenzie Pollock as senior W.H.O. representative.

In Geneva, the 26th session of the Executive Board opened on Oct. 25. Dr. Henrique M. Penido (Brazil) was elected chairman.

THE WORLD'S FOOD

"Food and population are two of the crucial determinants of the future of mankind. Freedom from hunger in the less developed countries of the world, however, is not simply a matter of regaining or maintaining pre-war levels of per caput production and consumption. ... Much greater increases in food production in these regions are needed before any real progress can be made in stamping out hunger and malnutrition. But increased food production must go hand in hand with general economic development so that consumers can afford the additional food and the better quality food they need."

In these words, taken from his foreword to F.A.O.'s latest annual report,[1] the Director-General summarises the agricultural problem confronting the greater part of the human race. While the highly developed countries continue to increase production (to the point of accumulating surpluses) by

A Medical Staff Residence

On Oct 18, at Odstock Hospital, Salisbury, a new residence for medical staff was officially opened by Mr P G Templeman, chairman of the Wessex Regional Hospital Board

The residence has 17 bed sitting rooms each with its own wash-hand basin and built in furniture A large lounge is separated from the dining room by sliding doors and meals are served from a small service kitchen adjoining the dining room There is a library away from the living-room area Two flats for married residents have been built beside the new residence The flats are furnished and centrally heated, and each has a lounge/dining room, kitchen, main bedroom, and spare room The cost of the whole scheme, including furnishings, was £35,000

Award for Medical Film

La Presse Médicale is again offering a prize (1000 NF) for a medical 16 mm film whose time of projection does not exceed 30 minutes Films should be sent to the journal, 120, boulevard Saint-Germain, Paris VI^{e}, before Feb 1

Caloric Balance in Man

The Nutrition Society is to hold a symposium on this subject on Saturday, Dec 17, at the Middlesex Hospital Medical School, London, W 1 The speakers will be Dr J V G A Durnin, Dr O G Edholm, Dr Raymond Greene, Dr I M Chalmers, Dr G C Kennedy, Dr A M Thomson, Dr F E Hytten, and Dr E M Widdowson Further particulars may be had from the hon programmes secretary of the society, Miss D F Hollingsworth, c/o Ministry of Agriculture, Fisheries and Food, Great Westminster House, Horseferry Road, S W 1

A meeting of the Biochemical Society is to be held on Friday, Nov 18, at 10 A M, at the Middlesex Hospital Medical School, London, W 1, when there will be a colloquium on histochemistry

Professor J B Duguid, who has lately retired from the chair of pathology in the University of Durham, has left for Malaya, where he is to be an adviser in histopathology under the Technical Cooperation Scheme of the Colombo Plan

The Association of Universities of the British Commonwealth (36, Gordon Square, London, W C 1) have published a list of fellowships, scholarships, and grants tenable at universities in the United Kingdom and a short list of awards tenable outside the United Kingdom Copies are being sent to universities and libraries and to other institutions on request

A committee meeting of the Group for Representation of the Views of Clinical Psychiatrists will be held on Thursday, Nov 10, at 5 30 P M, at Tavistock House North, Tavistock Square, London, W C 1

The London Medical Exhibition will be held in the New Hall of the Royal Horticultural Society, Westminster, from Nov 11 to 18

University College London will hold a reunion dinner at the college on Friday, Feb 17, for undergraduates or postgraduates who entered before 1918 Early applications for invitations should be made to the assistant secretary of the college, Gower Street, W C 1

From Nov 21 the address of the National Council for the Unmarried Mother and Her Child will be 255, Kentish Town Road, London, N W 5

Film about Handicapped Children—The Cine Club of Bristol, with the help of the South Western Regional Hospital Board and the Bristol education and health committees, has produced *Claremont*, which shows how children with spastic disabilities are educated and treated at a school at Claremont, Bristol The film, which is in 16 mm colour, has a sound commentary and lasts about 12 minutes The hiring fee is 1 guinea Applications should be sent to the medical officer of health, central health clinic, Tower Hill, Bristol, 2

CORRIGENDUM *Treatment of Urticaria*—The dose of proguanil ('Paludrine') mentioned in Sir Charles Dodds' letter of Oct 22 should have been 0 1 g (100 mg)

PREPARATION FOR THE PROFESSION *

The Present and the Future

JOHN ELLIS
M B E , M A , M D Cantab , F R C P
PHYSICIAN TO THE LONDON HOSPITAL, LONDON, E 1, AND TO THE PRINCE OF WALES GENERAL HOSPITAL, SECRETARY TO THE ASSOCIATION FOR THE STUDY OF MEDICAL EDUCATION

THERE are periods in the history of every country when the form of medical education is appropriate to the pattern of medical practice, and when that pattern is itself suitable to the medicine of the day, so that all knowledge can be applied effectively and ethically The standard of medicine is then as high as the degree of knowledge will allow, for medicine is in balance

Such a period comes to an end when there is a major advance in medical knowledge This advance passes very rapidly into practice and changes the pattern of it The change of practice then alters medical education, and if all goes well balance is restored

It is our particular good fortune to belong to medicine when it is again changing, or to be accurate has just changed The increase of knowledge has enforced specialisation—which itself ensures that knowledge will continue to grow at speed But, because in Britain no-one now lives far from a specialist, the general practitioner is prevented from doing much of the therapeutic job he was trained for Instead, he is left with an overwhelming amount of other problems of diagnosis, treatment, and prevention of disease, for which he was not trained He must transfer many patients to the care of another doctor, and he must be sure that he chooses the right specialty

While this increase in knowledge has thus been altering the pattern of practice, a change in the quality of knowledge has altered the doctor's concept of disease His attitude to diagnosis and treatment has become more scientific

But it must be noted that the change is in attitude to disease and not in attitude to the patient The problem of medical education is how to inculcate the scientific attitude while maintaining the highest standard of clinical skill and the most humanitarian concern for the patient as a person

* * *

It took us quite a long time to accept that with the coming of specialisation had come the end of general practice as we knew it, and also the end of the apprenticeship training which it had evolved for itself During that time an inevitable disruption of medical education has been intensified, more in some schools than others, by our continuing to produce general practitioners of a kind no longer required, by a system of apprenticeship to specialists which could not be successful anyway

However, that era of uncertainty as to the aims and objects of medical education is over It ended, in fact, several years ago when the General Medical Council in its *Recommendations* of May, 1957, officially stated that the aim is no longer to produce, by the time of qualification, a finished doctor of any kind In future medical education, for family doctors as well as for specialists, is to consist of two portions, undergraduate and postgraduate The significance of this radical change has not yet been fully appreciated for several reasons One is that a year of internship after qualification had become compulsory before 1957, and therefore the G M C 's action appeared to some to be no more than giving official blessing to something which had already happened A second is that, because medical education in this country is very rarely the primary concern of anyone, very many of those actively engaged in it have not yet read the G M C 's recommendations A third is that, in contrast to all its previous announcements the G M C did not specify in detail the nature of either a minimum undergraduate education or a minimum postgraduate training It very wisely left the onus of creating a new pattern of undergraduate education to each individual university and medical school, stating that this pattern must provide a sound basis for further study, by ensuring that the student not only acquires knowledge and clinical skill but also scientific method, he is to be given an education as well as a training This freedom is obviously essential if each of our 26 schools is to be able to develop new enterprise to the best of its capabilities, but initially of course it can act as a stimulus to progress only in those schools where the desire for progress exists

Thus, though medical education in this country has passed out of the phase of catabolism into the phase of anabolism, the signs of this are not to be seen in every university Some schools have set a new course for a new educational objective and are under way, some are drifting out of control, some are in the doldrums, and some are being blown far off course—even off their original course—by the contrary winds of contemporary medical practice It is inevitable that some will have a greater proportion of teachers who are firmly attached to the old form of training, but it is equally inevitable that these teachers, by their resistance to change, will demolish the pattern they seek to preserve It is natural that those schools which have been most successful in the application of one method should be the last to realise that it does not work any more The man who has for years travelled to his destination in a Rolls-Royce does not think of getting rid of it—until he discovers that others are getting there more satisfactorily in an aeroplane—with Rolls-Royce engines, of course

There is therefore cause for neither surprise nor lament in our present state of medical education, save in one respect Speed of adaption is obviously important and it does appear that this could be unnecessarily slowed in London About half of our medical students receive at least their clinical training in the 12 London medical schools Inequitable as it may seem, a faculty which has 12 separate schools is unable to move 12 times as fast as other universities, and is more likely to resemble a convoy whose speed is always that of the slowest ship It is always difficult for the commodore of a convoy to give the order " All ships to proceed at their best speed " It is true that in this case precisely that order has been given to the whole medical-education navy by the G M C , but there is in this country a well-known precedent for turning a blind eye to the receipt of a naval signal

---

* Extracts from the Wood-Jones lecture delivered in the University of Manchester Medical School on Feb 9, 1960 An abridged version of the lecture appears in the October issue of the *Manchester Medical Gazette*

However, all schools have been charged with the duty of adapting their education to meet modern conditions and needs, and most have already begun to do this.

At first sight they appear to be up against an insuperable difficulty—that of deciding how much knowledge and how much training is to be in the undergraduate years, and how much in the postgraduate. These questions seem difficult to answer in view of the fact that the responsibility for the postgraduate years is shared by the university with many other organisations, including the Royal Colleges and the Ministry of Health, and no one of them has sole authority. Furthermore, nobody could at the moment be precise as to how much knowledge and how much technical skill is necessary for the minimum effective practice of any branch of medicine, particularly as the function of the family doctor is not yet clearly defined.

But the fact that we do not know these things need not inhibit the reform of undergraduate education at all. For the aim of this, now, is first and foremost to *educate*—i.e., to give the student *not* knowledge but the power to utilise knowledge.

That he must know facts is obvious, and that in his early days he cannot find these out for himself but must be given them is equally obvious. His and his teachers' primary purpose, however, must be that he learns how to learn for himself. Therefore the factual content of the undergraduate period does not have to be any particular percentage of the total of medical knowledge, it has to be chosen for its relevance to future learning, not for its relevance to future practice. Equally important, the student's progress must be assessed *primarily* on his ability to reason and utilise knowledge, and not merely in terms of the amount he knows. Similarly his clinical proficiency must be judged on the soundness of his method, of which the correctness of the physical signs he elicits from a patient in an examination is but one indication. By the same token, if it be true, as is sometimes claimed, that the newly qualified of today know more than their predecessors ever did, this does not mean that all is really well with medical education.

If the object of undergraduate education is achieved, then gaps in knowledge and inadequacy of technique will be made good in the postgraduate period. If the object of undergraduate education is not achieved, then such gaps will probably remain for ever, and he will be largely denied the mastery of new data and the critical evaluation of new treatment. Though specialisation has come to stay, there is nothing the least static about the size or form of any particular specialty. The future happiness and success of specialist and general practitioner alike depend on his ability to learn and on his knowledge of general principles.

The following should be our objectives:

1. The student must learn how to learn for himself.
2. He must acquire a scientific method of thought—i.e., the power to reason and think critically.
3. He must achieve competence in clinical method—i.e., the techniques of obtaining information from patients.
4. He must gain an understanding of the responsibilities of a professional person.

If these objectives are reached the student will inevitably have built up a foundation of knowledge, including empirical knowledge. He will also have built a foundation of clinical experience, as regards the diagnosis, treatment, and prevention of disease on the one hand and the nature of man on the other. The exact content of the foundations of knowledge and experience will vary, but during the years of his postgraduate training, each student will be able to fill in those gaps relevant to his own future practice.

* * *

The undergraduate course of studies, thus freed from the need to include all or even any fixed percentage of knowledge and technique, can now, and must now, be based on considerations of the processes of learning.

This granted, it is at once evident that many different arrangements of studies have much to commend them in theory. Until they have been tried in practice, there can be no way of judging between them, and in any case the judgment can be no more than a clinical one. It is therefore idle to speak of the curriculum as though there is somewhere a correct arrangement which will be correct for every school and every student. The best curriculum for any particular school is that which enables it to make the best educational use of all its facilities and enables its students to progress through successive stages of learning, each with a clearly defined objective.

The number and sequence of stages, together with the purpose and content of each, will vary from school to school, but there are certain requirements which must be met in every stage everywhere:

1. Its purpose must be equally clear to both teachers and taught.
2. There must be deployed in it those incentives to study which are relevant to that purpose.
3. There must be built into it such forms of assessment of the student's progress as are appropriate to its content.

It goes without saying that other objectives, contrary incentives, and inappropriate tests should be excluded as rigidly as possible.

A course of studies of this kind cannot be made by a mere alteration of the timetable, even if this is done with educational objectives in mind. An entirely new attitude to teaching is required, and reform of the curriculum will be ineffectual unless there is also a reform of the method by which the curriculum is devised, applied, and constantly assessed. In my opinion this is no longer a matter of administration from the dean's office. There is required for each stage of the course a team of men who are responsible for it. They should represent all those departments most closely concerned with that stage, together with others whose advice could be helpful, even if they are not likely to teach in it themselves. For example, preclinical teachers should be concerned with the planning and assessment of predominantly clinical stages, and clinicians with the predominantly preclinical stages.

The team should, moreover, be representative of whole-time and part-time teachers, thus ensuring that the largest possible number of all kinds of teacher are closely involved in the educational effort. In this way cooperation can be achieved, for, instead of every department competing for what it feels is its rightful portion of the student's time, each becomes more concerned with what it has to contribute to the common purpose of each stage of the student's development. Furthermore, it is only when a teacher is able to appreciate the overall picture of that development that he can judge at what stage his own subject can make its best contribution. At present the resources of a special department are often squandered because students are routed through it too early or too late. Frequently also a student is able to attend a department for one period only, although it has something to offer him at several stages.

The effective planning, execution, and frequent assessment of every stage of a real course of studies is quite beyond the capabilities of any dean's staff or curriculum committee, but every school could muster a team for each stage Each team would be working towards a comprehensible and realisable objective, and would be able to define the content of knowledge and practical experience, deploy relevant incentives, and devise appropriate forms of assessment If integration of staff were ensured, the student would be helped to integrate his knowledge for himself without the aid of elaborate timetable innovations —and neither the autonomy of departments nor the freedom of individual teachers would be lost

* * *

I do not imagine that there will be anything very fanciful about the objectives of any stage, nor anything very intricate about its organisation It is possible already to see the general outline in several schools, and I would imagine that our traditional respect for sound clinical method based on an uninterrupted introduction to it will result in most universities preferring not to bring clinical experience very far forward in the course Indeed one would expect the first stage to continue to be one of the study of the normal, based on the old preclinical departments together with new ones, such as genetics The preclinical departments already form a kind of stage committee in most schools, but the addition to it of clinical and other representatives would, without necessarily taking part in the teaching at all, go far to create that unity of purpose, common outlook, and single terminology at staff level, without which students' work will remain divided into preclinical and clinical

Later stages must of course continue to be based upon existing firms and departments, but the great strength of these will be fully utilised if all concerned know what they are trying to do For example, a stage devoted to practice of clinical method must obviously use general inpatient firms, but the teachers on these firms would not be left, as now, to try to grapple with all aspects of medicine, and would have instead agreed limited objectives together with a chance to assess their results Nor would they have to contend and compete with synchronous courses of instruction, of which neither the content nor the purpose was known to them

It is in the later part of the present clinical curriculum that confusion and dissipation of effort are now so marked, particularly in regard to the purposes of outpatient experience and the contribution of special departments Order can be created again out of near-chaos by this simple process of organising stages of learning and experience by groups of teachers responsible for them

* * *

Our peculiar system of hospital staff structure has provided us with a teaching device in the firm, which ensures that a small number of students are closely attached to a teacher who is personally responsible for them and for the patients with whom they are concerned The student is thus constantly reminded that the care of the individual patient is the yardstick by which everything else is measured He is able to learn of the professional responsibilities of a doctor by the only possible method—observing the doctor fulfilling them Above all, the welding together of his education and practical training is assisted by his being required to focus both his integrated knowledge and his practical skill upon the problems of his patients He is enabled to acquire empirical knowledge and experience and at the same time be encouraged to learn scientific method because his teacher can set him this example, can excite his curiosity, and can guide him as an individual through his personal difficulties of learning

It is small wonder that other countries are endeavouring to create for educational purposes this firm system which considerations of hospital practice developed here Unfortunately with us it has been weakened by many factors which we have not tried to offset The first of these is simply that the clinical teacher has not got the time which is required for the care of both his patients and his students The second is that we have continued to think of the firm as an inpatient organisation

I believe that part of the last clinical year should be devoted to a stage of learning by experience under supervision, and that this should be based on attachment, for at least four months to a general medical firm, primarily in the outpatient department but extending into the wards In this students should be responsible for individual patients as they now are on the traditional inpatient firm Student and patient together would visit the special departments as the patient's condition demanded, and both would return to the doctor responsible for both

At this stage it should also be easy to extend the student's experiences outside the walls of the hospital, to give him an understanding of the patient as a whole, and demonstrate the relation of medicine to the community It is here that I would incorporate the general practitioner into the undergraduate teaching team, with membership of the committee responsible for this stage, so that he is conversant with the objectives which the student has been set and with the lines on which his development is planned

* * *

The provision of a new curriculum and a new type of administration, however, will not completely solve the problem of readapting medical education to present conditions of medicine The inclusion into undergraduate medical schools of all that is meant by university education is also necessary An essential requirement of this is interest in the individual student, so that he may develop in a stimulating intellectual atmosphere, with the encouragement and guidance of his teachers It would be idle to pretend that this is now possible in all our schools

If the medical student is to be a university student, then he must be treated as such, and the medical school must provide not merely teachers, a curriculum of classes, and an administration, but also an educational service It is not enough to have a tutorial system which is a mere adjunct to the other forms of teaching The system providing encouragement and guidance must not be separate from the system of reproof, which is represented by authority and vested in the dean Any dichotomy can only result in resentment of authority or frustration of encouragement But if all good incentives are mobilised and coordinated into one discipline, then progressive assessment of the individual becomes possible, and he can be given such help as he is known to need The medical school must have some kind of director of studies as well as a dean—just as our older university colleges have a senior tutor as well as a master—tutors and supervisors as well as teachers

The increased need for education requires also a new attitude to halls of residence In many universities these have long been recognised as a means whereby students can educate themselves by indirect contact with several faculties In his later years, however, the medical student

However, all schools have been charged with the duty of adapting their education to meet modern conditions and needs, and most have already begun to do this

At first sight they appear to be up against an insuperable difficulty—that of deciding how much knowledge and how much training is to be in the undergraduate years, and how much in the postgraduate These questions seem difficult to answer in view of the fact that the responsibility for the postgraduate years is shared by the university with many other organisations, including the Royal Colleges and the Ministry of Health, and no one of them has sole authority Furthermore, nobody could at the moment be precise as to how much knowledge and how much technical skill is necessary for the minimum effective practice of any branch of medicine, particularly as the function of the family doctor is not yet clearly defined

But the fact that we do not know these things need not inhibit the reform of undergraduate education at all For the aim of this now, is first and foremost to *educate*—i e , to give the student *not* knowledge but the power to utilise knowledge

That he must know facts is obvious, and that in his early days he cannot find these out for himself but must be given them is equally obvious His and his teachers' primary purpose, however, must be that he learns how to learn for himself Therefore the factual content of the undergraduate period does not have to be any particular percentage of the total of medical knowledge, it has to be chosen for its relevance to future learning, not for its relevance to future practice Equally important, the student's progress must be assessed primarily on his ability to reason and utilise knowledge, and not merely in terms of the amount he knows Similarly his clinical proficiency must be judged on the soundness of his method, of which the correctness of the physical signs he elicits from a patient in an examination is but one indication By the same token, if it be true, as is sometimes claimed, that the newly qualified of today know more than their predecessors ever did, this does not mean that all is really well with medical education

If the object of undergraduate education is achieved, then gaps in knowledge and inadequacy of technique will be made good in the postgraduate period If the object of undergraduate education is not achieved, then such gaps will probably remain for ever, and he will be largely denied the mastery of new data and the critical evaluation of new treatment Though specialisation has come to stay, there is nothing the least static about the size or form of any particular specialty The future happiness and success of specialist and general practitioner alike depend on his ability to learn and on his knowledge of general principles

The following should be our objectives

1 The student must learn how to learn for himself

2 He must acquire a scientific method of thought—i e , the power to reason and think critically

3 He must achieve competence in clinical method—i e , the techniques of obtaining information from patients

4 He must gain an understanding of the responsibilities of a professional person

If these objectives are reached the student will inevitably have built up a foundation of knowledge, including empirical knowledge He will also have built a foundation of clinical experience, as regards the diagnosis, treatment, and prevention of disease on the one hand and the nature of man on the other The exact content of the foundations of knowledge and experience will vary, but during the years of his postgraduate training, each student will be able to fill in those gaps relevant to his own future practice

* * *

The undergraduate course of studies, thus freed from the need to include all or even any fixed percentage of knowledge and technique, can now, and must now, be based on considerations of the processes of learning

This granted, it is at once evident that many different arrangements of studies have much to commend them in theory Until they have been tried in practice, there can be no way of judging between them, and in any case the judgment can be no more than a clinical one It is therefore idle to speak of the curriculum as though there is somewhere a correct arrangement which will be correct for every school and every student The best curriculum for any particular school is that which enables it to make the best educational use of all its facilities and enables its students to progress through successive stages of learning, each with a clearly defined objective

The number and sequence of stages, together with the purpose and content of each, will vary from school to school, but there are certain requirements which must be met in every stage everywhere

1 Its purpose must be equally clear to both teachers and taught

It is in the later part of the present clinical curriculum that confusion and dissipation of effort are now so marked, particularly in regard to the purposes of outpatient experience and the contribution of special departments. Order can be created again out of near-chaos by this simple process of organising stages of learning and experience by groups of teachers responsible for them.

* * *

Our peculiar system of hospital staff structure has provided us with a teaching device in the firm, which ensures that a small number of students are closely attached to a teacher who is personally responsible for them and for the patients with whom they are concerned. The student is thus constantly reminded that the care of the individual patient is the yardstick by which everything else is measured. He is able to learn of the professional responsibilities of a doctor by the only possible method—observing the doctor fulfilling them. Above all, the welding together of his education and practical training is assisted by his being required to focus both his integrated knowledge and his practical skill upon the problems of his patients. He is enabled to acquire empirical knowledge and experience and at the same time be encouraged to learn scientific method because his teacher can set him this example, can excite his curiosity, and can guide him as an individual through his personal difficulties of learning.

It is small wonder that other countries are endeavouring to create for educational purposes this firm system which considerations of hospital practice developed here. Unfortunately with us it has been weakened by many factors which we have not tried to offset. The first of these is simply that the clinical teacher has not got the time which is required for the care of both his patients and his students. The second is that we have continued to think of the firm as an inpatient organisation.

I believe that part of the last clinical year should be devoted to a stage of learning by experience under supervision, and that this should be based on attachment, for at least four months to a general medical firm, primarily in the outpatient department but extending into the wards. In this students should be responsible for individual patients as they now are on the traditional inpatient firm. Student and patient together would visit the special departments as the patient's condition demanded, and both would return to the doctor responsible for both.

At this stage it should also be easy to extend the student's experiences outside the walls of the hospital, to give him an understanding of the patient as a whole, and demonstrate the relation of medicine to the community. It is here that I would incorporate the general practitioner into the undergraduate teaching team, with membership of the committee responsible for this stage, so that he is conversant with the objectives which the student has been set and with the lines on which his development is planned.

* * *

The provision of a new curriculum and a new type of administration, however, will not completely solve the problem of readapting medical education to present conditions of medicine. The inclusion into undergraduate medical schools of all that is meant by university education is also necessary. An essential requirement of this is interest in the individual student, so that he may develop in a stimulating intellectual atmosphere, with the encouragement and guidance of his teachers. It would be idle to pretend that this is now possible in all our schools.

If the medical student is to be a university student, then he must be treated as such, and the medical school must provide not merely teachers, a curriculum of classes, and an administration, but also an educational service. It is not enough to have a tutorial system which is a mere adjunct to the other forms of teaching. The system providing encouragement and guidance must not be separate from the system of reproof, which is represented by authority and vested in the dean. Any dichotomy can only result in resentment of authority or frustration of encouragement. But if all good incentives are mobilised and coordinated into one discipline, then progressive assessment of the individual becomes possible, and he can be given such help as he is known to need. The medical school must have some kind of director of studies as well as a dean—just as our older university colleges have a senior tutor as well as a master—tutors and supervisors as well as teachers.

The increased need for education requires also a new attitude to halls of residence. In many universities these have long been recognised as a means whereby students can educate themselves by indirect contact with several faculties. In his later years, however, the medical student lingers on after his colleagues in other disciplines and tends to become more attached to a hospital than a university. Those who have no home in the vicinity may live in a hostel belonging to the medical school, but such hostels, as their name implies, are often thought of as merely lodging-houses conveniently near the wards. There is a great need for a change of attitude so that these places can play their full part in education. All students should spend some time in them, and not merely those who have difficulty in finding accommodation elsewhere. Far greater responsibility for the corporate life of the student body should then be given to the students themselves—a necessary experience for those who are going to carry heavy professional burdens but who now tend to be kept from both responsibility and community life up to the age of 24. In this field also the teaching staff have a large part to play, not as persons of authority or with administrative duties, but as senior members of a single professional and intellectual community.

In none of these things, which I believe to be so important, do I envisage any kind of spoon-feeding or wet-nursing of students. On the contrary, I am advocating that they be regarded much less as groups of overgrown schoolboys, and much more as individual adult members of a profession. Their reactions to the education offered must be regularly sought, as in most other countries it now is, and they should feel free to seek advice on problems of learning without fear of jeopardising their careers. In the past medical schools have been so concerned with teaching and examinations, that few facilities, either material or in personnel, now exist for education. The need for them is urgent, and they are required for the postgraduate as well as the undergraduate. The days have passed when any medical school can feel that its responsibility for a man has ended when he has passed his final examinations.

" Finals ", of course, are now a misnomer, for they merely indicate a qualification which is necessary before the student is in his last year of general internship, legally able to undertake the responsible practice under supervision of which this stage of experience is composed. It remains to be seen whether this stage should be increased in duration or advanced in time. But it is already a responsibility of the medical schools, though not one which they have been able fully to discharge. They will need to develop a much more active system of caring for the individual before they can do so.

It will only be when such a system has developed that many other features of a university education in medicine can be properly undertaken. For example electives, and opportunities for students to study a subject in depth by undertaking some piece of original work, depend for their full effect on adequate knowledge and guidance of the individual. Furthermore we have to regain in this country greater freedom for each student to develop in his own way and at his own speed. We have had an overcrowded curriculum for so long, that we have almost come at accept the idea of having the same timetable for every student. Worse still, the system of grants, by which most students are financed, has encouraged the idea, in both medical schools and grant-giving authorities, that there is a fixed maximum duration of studies which is properly common to all students. This is most unfortunate, because no-one has ever laid down more than a minimum period, and students do not all progress at the same speed. It is an odd paradox that by so rightly removing financial barriers to medical education in this country, we have at the same time removed from the individual his necessary freedom to vary from the average. In the United States where most students are privately financed, it is easier for a man to step off the production-line than it is here, where courses are repeated only by students who have done badly. In Sweden, where students can get State loans but not grants, the finishing line is an entirely personal affair. Our system of a class of students all taking their examination on the same day is regarded as most unusual.

* * *

In my view readaptation of medical education depends then, on (1) a course of studies, based on stages of learning together with relevant forms of assessment, (2) a more effective method of operating and maintaining the new curriculum, and (3) a university atmosphere. If these three things are provided, then undoubtedly new teaching techniques will emerge, or at all events we shall learn much more than we now know about the problems of education and the answers to them. In order to set our house in order, however, we do not need any more information than we now have. It is as useless as it is dangerous to wait for scientific proof that this or that is necessary, or that one scheme is better than another. This is a matter for clinical judgment. It is futile, and really only a form of escapism, to wait for some magic concrete plan which can be put into administrative effect and then forgotten.

The main obstacle to the full implementation of these three things is that very few teachers have enough time in which to give undivided attention to education. This can be remedied only by ensuring that part-time clinical teachers particularly, have enough sessions at the teaching hospital to enable them to practise clinical medicine, educate students, and engage in research. It is essential that this is done, if the country is to continue to have a high standard of medical service. It will inevitably cost money, but medical education is important. It alone can pass the advances of medicine on into effective practice. It is hopeless and wasteful to tackle it halfheartedly, and the most economical medical school, like the most economical hospital, is the one which sets out to be the best rather than the cheapest.

If in the National Health Service we can but make the terms and conditions of service of medical teachers relevant to the demands of education, we shall be able to mobilise a quite remarkable number of assets. Indeed, we should be in a far better position than any other country to solve the remaining problems of medical education.

* * *

It seems justifiable to expect, therefore, that after a long period of difficulty, we can now enter a period in which medical education will be once more in equilibrium with medicine. Certainly we should be able most successfully to give an education in medicine while retaining and even improving our ability to teach sound clinical method. But this does not mean that we will then be automatically giving a good preparation for medicine as a profession.

The basis of British practice is that each patient, whether in his home or at hospital, has one doctor who takes personal responsibility for him, but there is no doubt that this basis has been weakened, and that too often there is uncertainty as to who is really responsible for the patient. The doctor also has a responsibility to the community, which cannot be discharged merely by attending to individuals, and students have to be made aware of very many important duties of the profession other than that of diagnosing and treating disease. Lastly we have, always, the problem of the way in which we discharge our duties—the standard which the profession sets for itself and the nature of its corporate discipline.

In times of great change the standards of a profession are at risk, and all ethics have to be translated into new terms. Moral exhortation without content or direction is a futile thing, and today the student must be brought to share the problems which face his teacher both as concern the patient and the profession. He must learn that science, which he must use, searches only after truth and has no humanitarian ends in view, but he must also learn that in a *professional* community, unlike others, how a decision is made is more important than what is decided.

These problems are difficult—but only because medicine and the profession face a greater challenge than ever before. I would say that there has never been a better time than this in which to be a doctor: the opportunities, like the challenge, are greater than ever before. They are greater, I believe, in this country than in any other: we are in a better position to solve all our problems. But we cannot do so unless we set our sights high. We must accept that in a time of change the most idealistic approach is the most realistic. The pursuit of quality is the only aim proper to our profession and the only one it can afford to have.

THE EFFECT OF TEST FEEDS ON THE PLASMA LIPIDS

IT has been shown repeatedly that the type of fat in the diet affects the lipid content of the plasma. But the kind of investigation so far reported has several disadvantages.

The lipid changes have been produced by feeding particular oils and fats for several days, weeks, or even months, with the remainder of the diet under careful control, and in these circumstances several weeks elapse before the plasma lipids reach a constant level on the basal diet and again with each fat under test. Because during all this time the basal diet has to be rigidly controlled (Ahrens et al. 1957), many investigators have resorted to giving this diet as homogenised liquid feeds (Kinsell et al. 1953). Apart from the practical difficulties—especially for studies on normal people and outpatients—arising from long-continued control, the test materials may not be available in sufficient quantity, or may be unsuitable for long-term administration (e.g., tung oil). Moreover the effects of trace materials, and the relative importance of particular substances, are often difficult to evaluate when whole diets are being fed.

Hence, for identifying and defining the dietary factors that influence human lipid metabolism, there is need of a quick and reproducible biological test. This should last no more than 12 hours, for then only the test substance need be fed, the experimental conditions can be easily controlled, and any lipid changes can be compared with the effects of fasting for an equal period. Also, if the test is to be used as a method of biological assay, it should evoke reproducible responses in normal people and be sensitive to small changes.

Such a method, in this laboratory, has been in use for 4 years. Single test feeds of oils are given under standard conditions so that the effect of each oil on the plasma lipids can be quickly and clearly demonstrated. In this paper we illustrate the method first by describing the effect of arachis oil on the plasma glyceride, phospholipid, and cholesterol, and then by reporting the effects of various other oils.

Materials and Methods

The subjects were healthy male medical students (aged 19–33) on the same kind of diet and activity. They were not allowed dietary fat during the 12 hours before the experiment nor excessive fat on the previous day, and their fasting plasma was clear. A light breakfast of fat-free drinks, dry toast, and marmalade was allowed 2-3 hours before the experiment.

The Test Feed

50 g of the oil is given as a single feed, emulsified with 50 ml of skimmed milk and 50–100 ml of tap water, and flavoured if desired. (With feeds of less than 30 g the changes in the plasma lipids are small and inconsistent, while feeds above 60–70 g often cause nausea without proportionately increasing the plasma-lipid changes.) The emulsions must not be oily or thick and should be at room temperature; they should be drunk quickly, without breathing through the nose. The feeds are followed immediately by a strong-tasting drink, such as black-currant cordial, and by an apple.

A standard procedure without unpleasantness is essential, for, if the subjects are nauseated, the absorption of the feed is apparently delayed and the plasma-lipid changes are prolonged and inconsistent.

Collection of Blood Samples

Samples were taken before the feeds, and at 1½, 3½, 5½, 7–9, and 24 hours after them. The blood was obtained by venepuncture using siliconed syringes and run into 3.8% sodium-citrate solution buffered to pH 7.4 (18 ml of blood to 2 ml citrate solution), the plasma was separated immediately by centrifuging and then stored at 4°C. The analyses were begun next day.

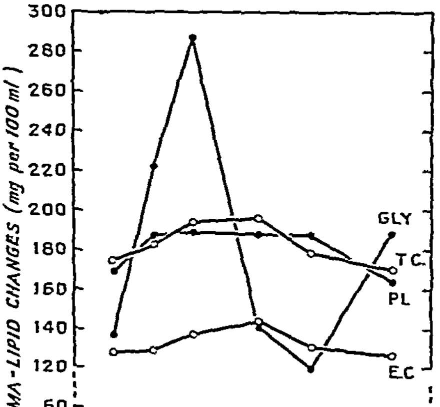

Fig. 1—The plasma-lipid levels before and after the 50 g meals of arachis oil (mean of six results).

GLY., glycerides; T.C., total cholesterol; PL., phospholipids; E.C., esterified cholesterol; F.C., free cholesterol; U.F.A., unsaturated fatty acids.

Methods of Analysis

Lipid phosphorus was determined by the method of Fiske and Subbarow (Hawk et al 1947), total and free cholesterol by that of MacIntyre and Ralston (1954), unesterified fatty acids according to Grossman et al (1954), and plasma total esterified fatty acids by the method of Morgan and Kingsbury (1959)

The entire series of plasma samples from each individual, plus the various standards, were analysed together in triplicate In this way fine differences between samples could be recognised The coefficient of variation of replicate samples by each method has always been less than 0 8% Total-cholesterol or *phospholipid changes of more than 3 mg per 100 ml* between the samples of one run, have therefore been accepted as significant

Effects of Arachis Oil

After single feeds of 50 g arachis oil the first observed change in the plasma lipids was an increase of glycerides, which reached a maximum 3–3$^{1}/_{2}$ hours after the feeds, after which the values fell rapidly for 3 hours and then more slowly and variably This increase in glycerides was accompanied by a slower rise and fall of the plasma cholesterol, phospholipids, and unesterified fatty acids, which reached their maximum at 3–6 hours after the meals, decreased gradually in the next 3 hours, and then fell very slowly The amount and the timing of the cholesterol and phospholipid changes were very similar The behaviour of the plasma lipids is shown in fig 1, which gives the average values obtained in six volunteers

It has been found that if too little of the oil is absorbed, or if the oil is absorbed too slowly, the subsequent changes in the cholesterol and phospholipids are inconsistent and unpredictable Adequate absorption of the oil, normally timed, is therefore a necessary condition of the experiment, and we do not consider it adequate unless the plasma glycerides rise between the fasting and $3^{1}/$ -hour samples and fall between the 3$^{1}/_{2}$-hour and $5^{1}/$ -hour samples Thus, if the plasma glycerides had not increased by more than 60 mg per 100 ml plasma (0 7 mMol per litre) at 3$^{1}/_{2}$ hours, and if over a third of this increase had not been removed by 5$^{1}/_{2}$ hours, the experiment was rejected The glyceride increases shown in our results represent, therefore, the differences between the fasting and 3$^{1}/_{2}$ hour samples, and the percentage clearances are the percentage removal of these increases between $3^{1}/$ hours and 5$^{1}/_{2}$ hours

In normal subjects with a clear fasting plasma and a

Fig 2—The changes in plasma phospholipid and cholesterol caused by the various oils (numbered as in table)

The effects of fractions A and B, cod-liver oil and of fasting, shown in the table are, for the sake of simplicity, not included in the figure.

PL.=phospholipids, T C.=total cholesterol, F C.=free cholesterol

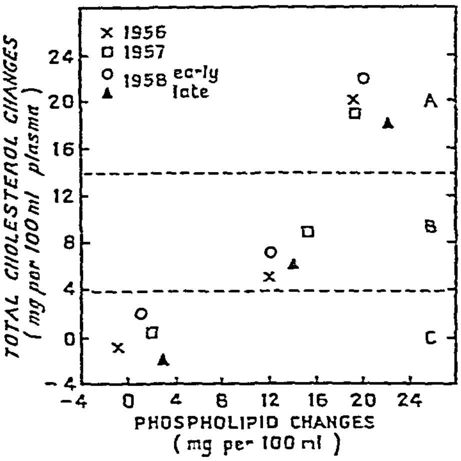

Fig 3

Fig 3—The response of three subjects to the same test feed when fed at intervals over 3 years

A, arachis, B, heated tobacco-seed oil, C, crude tobacco-seed oil The fasting plasma levels of the three subjects were A, phospholipids 98 mg per 100 ml, total cholesterol 235 mg, B, phospholipids 158 mg, total cholesterol 169 mg, C, phospholipids 222 mg, total cholesterol 254 mg

normal absorption of glyceride, plasma cholesterol and phospholipid reached their maximum 3–6 hours after the feed. The changes in phospholipids and cholesterol caused by the feeds can be expressed by the values

$$\frac{(3^1/_2\text{ hour}-\text{fasting})-(5^1/_2\text{ hour}-\text{fasting})}{2}$$

The figure obtained in this way we call the lipid response.

Effects of Various Other Oils

Single 50 g feeds of other oils were fed in the same way to normal volunteers The oils used, the number of experiments, and the lipid response are shown in the table.

Non-polymerised refined tung oil was supplied by Unilever Co The other oils were of edible grade and obtained from Unilever Co, H M Faure & Co, British Cod Liver Oils Ltd, and through Hess Products and Cyclo Chemicals Ltd

“Stored tobacco-seed oil” is crude oil which has been stored at 4 C in the dark for 9 months and ‘ heated tobacco-seed oil ’ is the crude oil heated by steam to 165 C under a high vacuum

“Fraction A” and “fraction B” were prepared from the fatty acids obtained by dehydrating ricinoleic acid Those liquid below 10 C (Hilditch 1956) were stored at 0 C for several weeks in the dark in an atmosphere of nitrogen, a solid fraction was separated by filtration at 0 C Both liquid and soil fractions were then frozen at 20 C, stored at 0 C for several weeks, and filtered as before The fractions solid at 0 C were combined and called fraction A, the combined fractions were called fraction C They were fed as ethyl esters

With all the oils, plasma glyceride rose by more than 60 mg per 100 ml and over a third of this increase was removed at $3^1/_2$–$5^1/_2$ hours But the different oils produced three different types of lipid response, and can accordingly be placed in three groups (table and fig 2)

Group 1—These raised the total-cholesterol and phospholipid levels by about 20 mg per 100 ml., without altering the ratios of total cholesterol to phospholipid or of free cholesterol to esterified cholesterol.

Group 2—The increases in total cholesterol and phospholipid were smaller, but the ratio of total cholesterol to phospholipid was reduced. The ratio of free cholesterol to esterified cholesterol was unaltered.

Group 3—With the oils in this group (crude and stored tobacco-seed oil) the levels of phospholipid and total cholesterol rose only very slightly or actually *fell* The level of free cholesterol consistently fell, but both the phospholipid and the free-cholesterol/esterified-cholesterol ratios were variable.

These different lipid responses were not associated with differences in the amounts of glyceride increase

In control experiments a fat-free diet, taken for 24 hours, reduced the levels of all the plasma lipids estimated.

Reproducibility of Lipid Response

Fig 3 shows the changes in cholesterol and phospholipid levels obtained with oils of the three groups Each volunteer received one oil four times, and on each occasion it produced the same kind of response, distinct from the effects of the other oils In the experiment recorded in fig 4, each of four volunteers took three different oils All four subjects showed the same type of lipid response to a given oil, and similar alterations in response when the oils were changed. (In fig 4, for simplicity, only the cholesterol changes are shown.)

Thus healthy people gave the same lipid response to a particular type of oil, even when the tests were separated

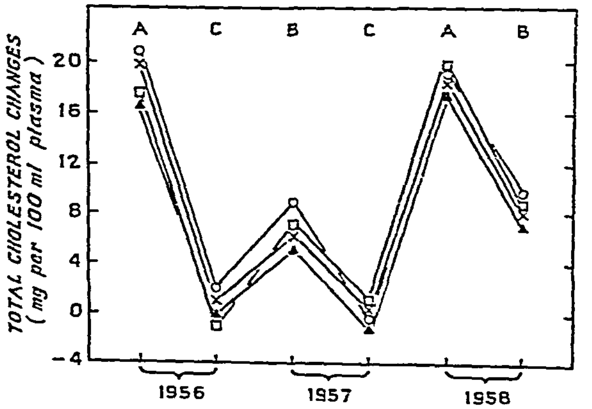

Fig 4—The “ swing ” of response in four subjects to three different types of oil (A, arachis B heated tobacco-seed oil C, crude tobacco-seed oil)

The fasting levels of total cholesterol in the four subjects were X, 181 mg per 100 ml, □, 211 mg ○ 183 mg, ▲, 189 mg by a year, and, by changing the oil, the volunteers could be " swung " to another response Clearly, the reproducibility of the results was not due to insensitiveness of the test This could in fact distinguish between the effects not only of different oils but even of the same oil before and after treatment by heat (table and fig 2)

Discussion

As a method of biological assay, the test feed has the advantage of simplicity, speed, and ease of control, and it enables us to ascertain the effects of single substances, using comparatively little material Their effects on plasma lipids are demonstrated not only (as in the longer experiments) by the changes in cholesterol and phospholipid but also by the relation of these lipids to one another and the relation of free cholesterol to esterified cholesterol The alterations in these relations are new findings which suggest that plasma-phospholipid and plasma-cholesterol levels are under separate physiological control Even in normal people the phospholipid/cholesterol ratio is not necessarily constant, and its different behaviour in response to group-1 and group-2 oils raises the interesting question whether it is ordinarily set by the diet

The different effects of crude and heated tobacco-seed oils is a further new finding, which will be discussed elsewhere The difference does not seem to be due to alterations in the fatty-acid composition of the oils

It is difficult to compare our results with those of other workers who have used single feeds for studying changes in the plasma lipids (Man and Gildea 1932, Lindholm 1956, Dole et al 1959), for, although Man and Gildea, for example, recorded similar phospholipid changes, their aim was to see whether lipid changes did in fact occur, and not to create a standard method of biological assay (Kingsbury 1958) Reasons why our findings may differ from those of the longer (more usual) experiments are numerous

1 The oils may have been subjected to different treatment (compare our different results with crude and heated tobacco-seed oils)

2 Most of the other work has been done on patients, whereas ours was on normal subjects

3 The results reported here concern only the period of lipid increase *immediately following the fatty meals*, whereas the results of long-term experiments must be the algebraic sum of varying lipid absorption, plasma-lipid increases, and clearance of lipids from the blood

4 The two methods may be sensitive to different variables

5 Whereas our results describe changes from a standard basal condition, the changes in the long-term experiments result from altering one diet for another This point can be illustrated by the fact that in the long experiments corn oil has so often caused an immediate and progressive *fall* in the plasma-cholesterol level, whereas in our experiments it caused a rise

It is all the more interesting, therefore, that our results should in many ways resemble those of Ahrens (1957), using the longer method In both investigations oils having iodine values above 100 produced low levels of plasma cholesterol, whereas with oils which have iodine values below 90 the cholesterol level increased with the saturation of the fat (see table) Whale, pilchard, and cod-liver-oil—which are rich in polyunsaturated acids but not in those essential for the normal health of animals (Thomasson 1953)—gave the same kinds of lipid responses as the edible vegetable oils (corn, soya, sunflower) whose high content of unsaturated acids is composed mainly of " essential " fatty acids This is similar to the results of Ahrens (1959)

In view of the similar effect of fish oils and vegetable oils on the plasma-cholesterol, it is interesting to reflect that, though an increase of tri-unsaturated acids in the tissue lipids of animals is strong evidence for a deficiency of the essential fatty acids (Jorgensen and Holman 1958), this accumulation of trienes has been reversed by cod-liver oil (Rieckenhoff et al 1949, Dam et al 1959), and that though this oil is rich in polyunsaturated acids, it has a very low essential-fatty-acid activity when assessed conventionally in terms of a normal skin in animals Thus it seems that many of the polyunsaturated acids, such as those found in cod-liver oil, may not only lower the blood-cholesterol level but also correct fatty-acid deficiencies

As conventionally defined, a " non-essential " acid very similar in physical properties to the " essential " linoleic acid is its *cis-trans* isomer, which has a melting-point of about −3°C (Privett et al 1955) or up to 7°C (Jackson et al 1952) Unfortunately it cannot yet be made in quantities sufficient for feeding experiments, but, as an alternative, we hoped to obtain low-melting-point isomers of linoleic acid from dehydrated ricinoleic acids (Hilditch 1956) Ultraviolet spectroscopic analysis (Hilditch et al 1951) of our fractions A and B showed that about 60% were linoleic acid or its isomers, of which about half were conjugated, probably the *cis-trans* isomers were concentrated in fraction B (melting-point 0–10°C) As both these fractions raised the plasma lipids only slightly (see table) it appeared that the lipid response to the natural *cis-cis* linoleic acid (approximately 70% of tobacco-seed oil) was neither prevented nor obscured by its conjugated or other isomers

Our results with tung oil are not at present explainable Sinclair (1959) has suggested that it should have the same effects as other non-essential oils of equal unsaturation, but this ignores its undoubtedly different properties, as evident in its chemical reactivity, rate of oxidation, and absorption spectra in the ultraviolet Possibly the biological action of conjugated fatty acids of this type differs from that of non-conjugated acids of equal unsaturation

The reasons for the different effects of the various oils are not yet established, but we cannot see why many factors in oils should not act in different ways For instance, the amount of the biologically essential linoleic acid usually given as a dietary supplement is about 50 g a day (Olson et al 1958) This would be about 5–10% of the total dry weight of the daily diet of our volunteers and probably about 10% of a patient's hospital diet In animals, however, severe essential-fatty-acid deficiency can be corrected by less than 0 5% of linoleic or arachidonic acid in the diet (Holman 1950)—an amount of arachidonic acid which is said to have no effect on the plasma lipids of man (Keys et al 1959) It may be that, in large amounts, unsaturated acids (both essential and non-essential) alter the physicochemical properties and hence the metabolism of their esters (glycerides, cholesterols, phospholipids, &c) (Klein and Martin 1959) This need not exclude a simultaneous correction of any existing fatty-acid deficiency (Fulco and Mead 1959)

In addition, an effect from the non-saponifiable or trace components of an oil cannot be excluded, and this may be the reason why crude tobacco-seed oil and heated tobacco-seed oil (though we have found no difference in their fatty-acid composition) have different effects

by a year, and, by changing the oil, the volunteers could be "swung" to another response Clearly, the reproducibility of the results was not due to insensitiveness of the test This could in fact distinguish between the effects not only of different oils but even of the same oil before and after treatment by heat (table and fig 2)

Discussion

As a method of biological assay, the test feed has the advantage of simplicity, speed, and ease of control, and it enables us to ascertain the effects of single substances, using comparatively little material Their effects on plasma lipids are demonstrated not only (as in the longer experiments) by the changes in cholesterol and phospholipid but also by the relation of these lipids to one another and the relation of free cholesterol to esterified cholesterol The alterations in these relations are new findings which suggest that plasma-phospholipid and plasma-cholesterol levels are under separate physiological control Even in normal people the phospholipid/cholesterol ratio is not necessarily constant, and its different behaviour in response to group-1 and group-2 oils raises the interesting question whether it is ordinarily set by the diet

The different effects of crude and heated tobacco-seed oils is a further new finding, which will be discussed elsewhere The difference does not seem to be due to alterations in the fatty-acid composition of the oils

It is difficult to compare our results with those of other workers who have used single feeds for studying changes in the plasma lipids (Man and Gildea 1932, Lindholm 1956, Dole et al 1959), for, although Man and Gildea, for example, recorded similar phospholipid changes, their aim was to see whether lipid changes did in fact occur, and not to create a standard method of biological assay (Kingsbury 1958) Reasons why our findings may differ from those of the longer (more usual) experiments are numerous

1 The oils may have been subjected to different treatment (compare our different results with crude and heated tobacco-seed oils)

2 Most of the other work has been done on patients, whereas ours was on normal subjects

3 The results reported here concern only the period of lipid increase immediately following the fatty meals, whereas the results of long-term experiments must be the algebraic sum of varying lipid absorption, plasma-lipid increases, and clearance of lipids from the blood

4 The two methods may be sensitive to different variables

5 Whereas our results describe changes from a standard basal condition, the changes in the long-term experiments result from altering one diet for another This point can be illustrated by the fact that in the long experiments corn oil has so often caused an immediate and progressive fall in the plasma-cholesterol level, whereas in our experiments it caused a rise

It is all the more interesting, therefore, that our results should in many ways resemble those of Ahrens (1957), using the longer method In both investigations oils having iodine values above 100 produced low levels of plasma cholesterol, whereas with oils which have iodine values below 90 the cholesterol level increased with the saturation of the fat (see table) Whale, pilchard, and cod-liver-oil—which are rich in polyunsaturated acids but not in those essential for the normal health of animals "essential" fatty acids This is similar to the results of Ahrens (1959)

In view of the similar effect of fish oils and vegetable oils on the plasma-cholesterol, it is interesting to reflect that, though an increase of tri-unsaturated acids in the tissue lipids of animals is strong evidence for a deficiency of the essential fatty acids (Jorgensen and Holman 1958), this accumulation of trienes has been reversed by cod-liver oil (Rieckenhoff et al 1949, Dam et al 1959), and that though this oil is rich in polyunsaturated acids, it has a very low essential-fatty-acid activity when assessed conventionally in terms of a normal skin in animals Thus it seems that many of the polyunsaturated acids, such as those found in cod-liver oil, may not only lower the blood-cholesterol level but also correct fatty-acid deficiencies

As conventionally defined, a "non-essential" acid very similar in physical properties to the "essential" linoleic acid is its *cis-trans* isomer, which has a melting-point of about −3°C (Privett et al 1955) or up to 7°C (Jackson et al 1952) Unfortunately it cannot yet be made in quantities sufficient for feeding experiments, but, as an alternative, we hoped to obtain low-melting-point isomers of linoleic acid from dehydrated ricinoleic acids (Hilditch 1956) Ultraviolet spectroscopic analysis (Hilditch et al 1951) of our fractions A and B showed that about 60% were linoleic acid or its isomers, of which about half were conjugated, probably the *cis-trans* isomers were concentrated in fraction B (melting-point 0–10°C) As both these fractions raised the plasma lipids only slightly (see table) it appeared that the lipid response to the natural *cis-cis* linoleic acid (approximately 70% of tobacco-seed oil) was neither prevented nor obscured by its conjugated or other isomers

Our results with tung oil are not at present explainable Sinclair (1959) has suggested that it should have the same effects as other non-essential oils of equal unsaturation, but this ignores its undoubtedly different properties, as evident in its chemical reactivity, rate of oxidation, and absorption spectra in the ultraviolet Possibly the biological action of conjugated fatty acids of this type differs from that of non-conjugated acids of equal unsaturation

The reasons for the different effects of the various oils are not yet established, but we cannot see why many factors in oils should not act in different ways For instance, the amount of the biologically essential linoleic acid usually given as a dietary supplement is about 50 g a day (Olson et al 1958) This would be about 5–10% of the total dry weight of the daily diet of our volunteers and probably about 10% of a patient's hospital diet In animals, however, severe essential-fatty-acid deficiency can be corrected by less than 0 5% of linoleic or arachidonic acid in the diet (Holman 1950)—an amount of arachidonic acid which is said to have no effect on the plasma lipids of man (Keys et al 1959) It may be that, in large amounts, unsaturated acids (both essential and non-essential) alter the physicochemical properties and hence the metabolism of their esters (glycerides, cholesterols, phospholipids, &c) (Klein and Martin 1959) This need not exclude a simultaneous correction of any existing fatty-acid deficiency (Fulco and Mead 1959)

In addition, an effect from the non-saponifiable or trace components of an oil cannot be excluded, and this may

Summary and Conclusions

A method for the biological assay of dietary lipids is described in which changes in the plasma glycerides, cholesterol, and phospholipids are measured after single 50 g. feeds of the fat under investigation. Plasma samples are collected before and 1½, 3½, 5½, 7–9, and 24 hours after the test feed.

The conditions for success are a period of fat deprivation and a clear fasting plasma before the experiment, a standard method of feeding, the avoidance of nausea, and adequate absorption of the oil. The criterion of adequate absorption is a rise in plasma glycerides by more than 60 mg. at 3½ hours, of which increase over a third must have been removed by 5½ hours.

The plasma-cholesterol and plasma-phospholipid changes produced by the feeds are called the lipid response. This response differs with different oils, the characteristic changes being reproducible both in different subjects and in the same subjects after long intervals.

The method has the advantage of needing only small amounts of material, of being quick and sensitive, of easily allowing experimental controls, and of not requiring special diets.

It is not offered as an alternative to long-term experiment, but as a supplementary method especially useful for rapid biological assays.

New contributions by this method are (1) the finding that different oils have different effects on the plasma phospholipid cholesterol ratios, (2) the use of these changing ratios to classify the type of lipid response to the experimental fat, and (3) the different effects of crude and heated oils.

The reasons for the different effects of the various oils are not known, but they are unlikely to be all due to one type of substance or property.

We wish to thank the volunteers, without whom the work would have been impossible and who received no recompense for much unpleasantness, Mr W Dorrel and Mr P A Dupont for technical assistance, Prof. C G Roo and Mr R W Best (Unilever Ltd.) for advice and interest, and Bush & Co for generous gifts of flavourings. Part of this work was included by K. J. K. in a thesis for the degree of doctor of philosophy, London University, 1958

MYOCARDIAL INFARCTION AMONG MEMBERS OF COMMUNAL SETTLEMENTS IN ISRAEL

DANIEL BRUNNER
M.D. Vienna

GIDEON MANELIS
M.D. Geneva

From the First Medical Department and Research Laboratory for Degenerative Cardiovascular Diseases, Government Hospital, Jaffa, Israel

THE incidence of ischæmic heart-disease differs strikingly between different countries (World Health Organisation 1956) and even in a single country between different ethnic and social groups (Brock and Bronte Stewart 1955, Brunner and Löbl 1957, 1958, Dreyfuss 1953, Toor et al. 1957).

We have sought to examine the influence of physical exercise on the incidence of myocardial infarction in the Kibbutzim and Kvutzoth. These are communal settlements in Israel, whose members are ethnically homogeneous and where the environmental conditions (standard of living, diet, housing, cultural activity, and recreation) are virtually uniform. No difference is made between teachers, clerks, businessmen, local political leaders, drivers, fishermen, masons, and agricultural workers.

Material and Methods

This survey covers the incidence of myocardial infarction in the ten years up to Dec. 31, 1959, in 8500 people (4500 men and 4000 women) who at the end of 1949 were aged 30–55.

One of us (G. M.) visited each of the 58 settlements in which these people lived. Because of the comprehensive medical service in these settlements, we had no difficulty in obtaining data on all fatal cases (sickness certificates, hospital case-records, postmortem reports, and electrocardiograms) and surviving patients who had had myocardial infarcts (detailed clinical examination and electrocardiograms). All patients except 2 were admitted to hospital soon after the infarction. Thus the diagnosis of myocardial infarction, whether the patient survived or died, was based on the clinical picture and on an unequivocal electrocardiographical diagnosis. As electrocardiographic proof of myocardial infarction we accepted only typical Q waves or typical T waves, or both together. Not included in this review are patients who presented the clinical picture of angina pectoris with or without the electrocardiographic pattern of coronary insufficiency.

Findings

In the ten-year period there occurred, among the population of 8500, 111 cases of myocardial infarction, 34 patients died and 77 survived. Of the 4000 women, only 9 had infarction, and of these 2 died and 7 survived.

In the communal settlements of all persons in the age-group of the sample, 30% are engaged in sedentary work and 70% in non-sedentary work. By contrast, in the cases of myocardial infarction, of the 34 who died 19 were engaged in sedentary work, and, of the 77 who survived, 42 were engaged in sedentary work. The group of non-sedentary workers included also those doing very light bodily work, such as that of confectioner or light physical work in industrial factories. When classifying the men according to their occupation, we took into account work done by the patient for at least four years before the attack. Particular care was taken not to include in this or any other group men who had changed their occupation as a result of their illness.

For non-sedentary male workers the annual incidence was 1·36 per 1000, whereas for sedentary male workers the annual incidence was 4·1 per 1000. Thus the incidence was three times greater in the sedentary workers. The

mortality-rate was likewise three times greater in this group

Comment

These data support those of Morris (Morris et al 1953, Morris and Crawford 1958) indicating the preventive influence of bodily activity

Jewish people are reputedly especially prone to ischaemic heart-disease (Epstein et al 1957), but our findings do not support this belief The annual incidence of myocardial infarction among the sedentary Jewish workers whom we studied is almost identical with that in London sedentary workers observed by Morris et al (1953) On the other hand, the incidence of myocardial infarction among non-sedentary workers in Kibbutz (0 8 per 1000 men per year) is only half the incidence among London postmen who walked in their daily work (1 6 per 1000 men per year)

These findings underline the importance of physical exercise as a factor in the prevention of myocardial infarction

This research was carried out with the aid of a grant from the Fund for Applied Research of the Israeli Ministry of Health and from the Research Foundation of the General Federation of Jewish Labour in Israel (Histadruth)

INVOLUTIONARY SCLEROSIS AND DIASTOLIC HYPERTENSION

EFFECT OF ENVIRONMENTAL CHANGE

A M Cohen
M D Amer Univ Beirut
LECTURER IN MEDICINE

E Neumann
M D Lausanne
INSTRUCTOR IN OPHTHALMOLOGY

I C Michaelson
Ph D Glasg , F R F P S , D O M S
PROFESSOR OF OPHTHALMOLOGY

From the Department of Internal Medicine B, and Department of Ophthalmology, Rothschild Hadassah University Hospital, Jerusalem, Israel

Indirect evidence, based on hospital statistics, has shown that arteriosclerotic cardiovascular disease is more common among the Yemenite community who have lived in Israel for a long time than among new immigrants from Yemen (Dreyfuss 1953, Toor et al 1960) The blood-cholesterol and blood-phospholipids are higher among Yemenites settled in Israel than among new immigrants from Yemen (Toor et al 1954, Brunner et al 1955) It was shown by one of us that there is practically no diabetes mellitus among new immigrants from Yemen, while among those settled in Israel for more than twenty-five years, its prevalence is comparable to that among Jews from the western world (Cohen 1960)

The purpose of our investigation was to determine whether the difference in environment between Yemen and Israel also affects the prevalence of involutionary sclerosis and diastolic hypertension among these contrasting groups Yemenite Jews form particularly suitable material for this study, being a homogeneous group with little or no intermarriage with other groups Constitutional factors, therefore, cannot affect the clinical differences between the settled and the new immigrant groups

In order to have the groups unselected, the entire Yemenite population above the age of 30 in chosen areas were visited in their homes The diagnosis of diastolic hypertension was based on manometric examination, and that of involutionary sclerosis on ophthalmoscopic examination of the retinal vessels This procedure seems to be as reliable as any one method for the diagnosis of involutionary sclerosis, and is probably the most suitable for a house-to-house examination It is, however, appreciated that changes in the retinal blood-vessels do not necessarily indicate changes in the entire vascular tree, nor does the absence of any change rule out the possibility of arteriosclerosis in other parts of the body

Material and Methods

The survey was carried out during 1959 The first group, the " new immigrants ", consisted of the entire population, over the age of 30, in two settlements near Jerusalem, Yishi and Noham They had all immigrated from the Yemen within the past ten years The group contained 147 persons, 70 men and 77 women The second, the " settled " group, consisted of the entire population, over the age of 30, in two Jerusalem quarters, Nahalat Ahim and Mishkenot They all had lived in Israel for over twenty-five years, and some were born there This group contained 125 persons, 55 men and 70 women All examinations were carried out at their homes Age, sex, and time of arrival to this country were noted A short physical examination was carried out in each case Resting blood-pressure was taken several times Urine was examined for albumin with sulphosalicylic acid, and for glucose with glucose reductase (' Test Tape ', Lilly)

Diastolic hypertension was considered to be present when the systolic pressure exceeded 140–150 mm Hg, and the diastolic 90 mm Hg The criteria for involutionary sclerosis were (*a*) narrow retinal arteries, (*b*) unusually straight course of these vessels, and (*c*) narrowness of their bifurcations Many of these cases showed slight variations in calibre of the arteries, and some changes at the arteriovenous crossings These were not, however, thought to be essential for the diagnosis of involutionary sclerosis The arteries were considered to

TABLE I—AGE (YEARS) AND SEX-DISTRIBUTION IN THE TWO GROUPS

—	30–55 years				Over 55 years				Total	
	M		F		M		F		M	F
	Number of patients	Average age	Number of patients	Average age	Number of patients	Average age	Number of patients	Average age		
New	44	40 0 ± 7 8*	59	41 5 ± 7 3	26	69 2 ± 7 0	18	67 1 ± 8 0	70	77
Settled	30	40 7 ± 7 5	36	41 9 ± 8 3	25	68 1 ± 6 9	34	66 2 ± 7 1	55	70

* Standard deviation of the mean

e narrow and straight if at least 2 out of the main 4 vessels n each fundus were found to be affected, and the bifurcations were considered narrow if the majority of them were ffected There is a certain subjective element in the iagnosis of involutionary sclerosis in the retina, and there- ore only cases where there was no doubt of the retinal iagnosis were included 60% of all cases of involutionary clerosis showed systolic hypertension Fisher's exact nethod for a 2×2 contingency table was used for tatistical analysis

Results

Table I shows the average age in each age-group for men nd women is almost the same in the " settled " and " new mmigrants " groups

4 cases of diastolic hypertension (3 women and 1 man) vere found among the new immigrants, and 17 (7 men, 10 women) among the settled group There was no statistical difference between men and women in each age-group of the " new " and " settled " groups in the prevalence of diastolic hypertension or involutionary sclerosis, except for ages 30–55 Except in this group, nen and women were grouped together (Fisher's exact nethod yields relatively low probabilities even for each sex and age group separately) The prevalence of hypertension is shown in table II

TABLE II—PREVALENCE (AS A PERCENTAGE) OF DIASTOLIC HYPERTENSION IN THE TWO GROUPS

—	30–55 years	Over 55 years
New	1% (0 M, 2 F)	7% (4 M 11 F)
Settled	7 5% (7 M 8 F)	20% (20 M, 21 F)
P	0 03	0 04

Proteinuria was found once in the 4 hypertensives among the new immigrants, and five times in the 17 hypertensives among settled Yemenites

It is of interest that, though there were no diabetics among the new immigrants, there were 9 among the settled group (6 men and 3 women), 8 being more than 60 years old

The percentage of cases with involutionary sclerosis, but without diastolic hypertension or diabetes, among the new immigrants and old settlers is given in table III

TABLE III—PREVALENCE (AS A PERCENTAGE) OF RETINAL INVOLUTIONARY SCLEROSIS IN THE TWO GROUPS

—	30–55 years			Over 55 years		
	Total	M	F	Total	M	F
New	3%	0	5	8%	9	6
Settled	18 %	7	27	34%	26	33
P		0 16	0 002		0 006	

There was a statistically significant difference in the prevalence of involutionary sclerosis between the " new " and " settled " in the age-group 55+ and between " settled " and " new " women in the age-group 30–55 No significant difference was found in the men of the age-group 30–55

Discussion

It can be seen that there is a greater prevalence of diastolic hypertension, and of the ageing process as seen in the retina, among the Yemenites who have lived in Israel for over 25 years as compared with Yemenite new immigrants who have not lived for more than 10 years in the country The findings parallel the differences in the prevalence of diabetes, and in the blood-cholesterol and blood-phospholipids estimates between both groups and confirm the impression that cardiovascular disease and arteriosclerosis are more prevalent in the settled group

There is a great difference between the conditions of life in Israel and in Yemen, and there is little doubt that the different prevalences of hypertension and involutionary sclerosis between the two groups is the result of these differences The lack of intermarriage with other groups of Jews eliminates constitutional and genetic factors as an explanation of the differences The main differences between the two groups are in food habits and in the general strain of living to which they are exposed The latter can be best described as the ambition for a higher standard of living, and the general " speeding-up " involved in the Western style of culture

We describe here a method of measuring and recording the changes in radiographic lung density during respiration We suggest that the function of a localised area of lung may be studied by correlating these density variations with simultaneous spirometric recordings

Attempts have been made by Kjellberg et al (1950) to study variations in pulmonary blood-flow by recording lung-density variations, using an electrokymographic method described by Engstrom et al (1949) Marchal et al (1946, 1949, 1959) have studied lung-density variation during respiration, paying particular attention to the pulsation of the pulmonary arteries These authors have also found that the variation in density of each lung during respiration correlates well with bronchospirometric findings Other workers (Simonin et al 1950, 1951) have attempted to study lung function by photometric comparison of the film densities on inspiration and expiration of similar areas of lung, radiographed through a kymographic grid They have compared this method with electrokymographic measurements of lung density, and compared both methods with bronchospirometry

Methods

Description of Apparatus

The apparatus is illustrated in figs 1a and b

The image of the lung field, formed on the phosphor of a 5-in Philips image-intensifier, is viewed through a binocular eyepiece to establish the exact area under examination A photomultiplier (R C.A type 913) in a special mounting is substituted for the eyepiece An iris diaphragm is fitted to the

patient Fig 1 illustrates our technique, using a dialyser with 18 m of cellophane tubing

The perforated metal cylinders which form the screens for the cellophane spiral must be reinforced by a metal " skeleton " The inner cylinder would otherwise be damaged during operation by the considerable pressure resulting from application of positive pressure over a large surface Blood is pumped from the patient by a ' Sigma ' finger pump with adjustable speed (fig 1, P) The pump can be adjusted to ' occlusive " setting, which makes the rate of blood-flow relatively independent of the pressure head in A A is a simple manometer system which records the blood-pressure before it enters the proximal cellophane coils S is the cellophane spiral where ultrafiltration takes place This spiral is immersed in bath fluid B is a manometer system which records the blood-pressure as it leaves the distal coils The outflow tube can be narrowed by an adjustable screw, K, whereupon the pressure in B and in A will increase By using manometers A and B various pressure-flow relations can be recorded, this system also allows the blood flow-rate to be measured in vitro

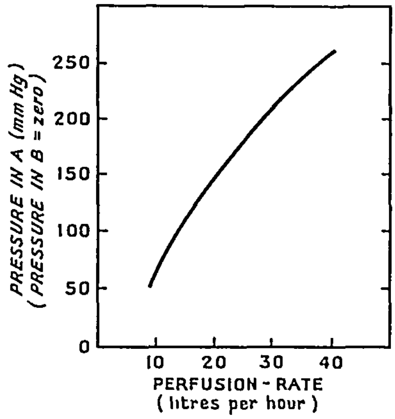

Fig 2—Pressure-flow relations in ultrafiltration with an 18 m cellophane tube, and without constriction of outflow tube
The pressure in A reaches 200 mm Hg at a perfusion-rate of 30 litres per hour

Fig 2 shows the increase in pressure in A when the rate of flow is increased without raising the pressure in B by creating a resistance at K As maximum safe pressure we have empirically chosen 200 mm Hg Above this pressure the inner cylinder may be damaged (even when reinforced) or the cellophane tube may leak 200 mm Hg pressure in A is achieved with a flow-rate of 30 litres per hour

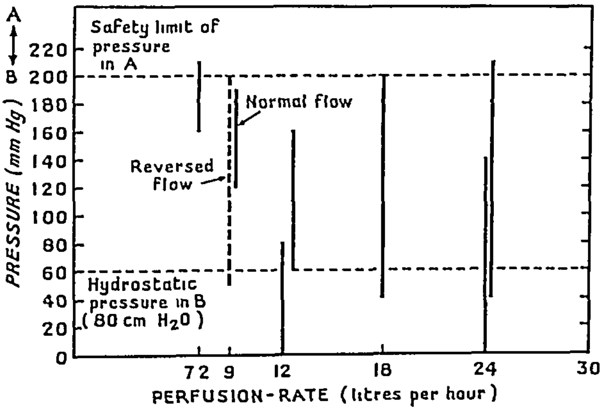

Fig 3—Pressure-flow relations with an 18 m cellophane ultrafiltrator
Pressure at B is variably increased Only moderate perfusion rates allow the pressure at B to increase considerably without excessive increase at A

Fig 3 shows the pressure-flow relations if the resistance at R is increased Each vertical column represents at the top the pressure in A, and at the bottom the pressure in B, at a certain flow-rate High flow-rates do not permit high pressures in B, because the pressure in A would then pass the safety limit Ultrafiltration will be most efficient, however, if it takes place along the whole length of the cellophane tubing, and for this a high pressure is necessary in B This can only be obtained with a moderate perfusion-rate Too low a rate is unfavourable because the blood becomes excessively dehydrated, and ultra filtration is handicapped by increasing colloid-osmotic pressure A moderate flow of 10–12 litres per hour seems to be best for ultrafiltration If the direction of blood-flow is reversed (from below upwards) the pressure difference between A and B increases considerably because the hydrostatic pressure of the bath fluid has now to be overcome at A The resulting mean pressure $\frac{(A+B)}{2}$ is lower than with a normal flow, hence the direction of the blood-stream should be downwards

The efficiency of dialysis is greater if the flow-rate is increased (fig 4) High perfusion-rates (20–30 litres per hour) result in rapid clearances and consequently short dialyses If dialysis is combined with ultrafiltration, however, moderate flows of 10–12 litres per hour seem preferable

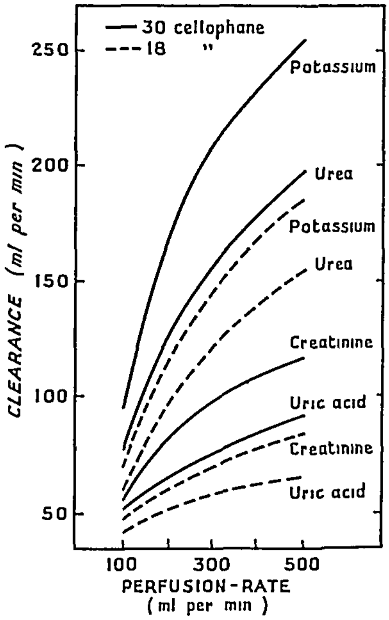

Fig 4—In-vitro clearances of the Alwall kidney at different perfusion-rates

We observed in vitro a water extraction of about 300 ml per hour—a figure which correlates well with our clinical experience and with other published data Higher rates of dehydration may lead to shock and hypotension The above rate was well tolerated by overhydrated patients, and it did not cause hypotension, although hypertension was sometimes reduced to normal

Summary

The artificial kidney of the Alwall type can be used for controlled ultrafiltration by creating a pressure difference between the extracorporeally circulating blood and the bath fluid

The optimal flow-rate for ultrafiltration is lower than that for dialysis

In clinical ultrafiltration water extraction of 300 ml per hour did not lead to hypotension if the patient was overhydrated

STAPHYLOCOCCAL PNEUMONIA IN THE NEONATAL PERIOD

UNIVERSITY LECTURER IN PATHOLOGY

THE DEPARTMENT OF PATHOLOGY, UNIVERSITY OF CAMBRIDGE

The pattern of tissue reaction to microbial infection varies with the virulence of the organism, the resistance of the host, and occasionally with the portal by which the organism gains access Neonatal lung infection with the staphylococcus illustrates this point

We describe here eight examples of staphylococcal pneumonia in the neonate which occurred during the period March, 1958, to August, 1959 They illustrate the often fulminant character of the infection and the variety of histological appearances in the lungs, and emphasise the need for the diligent use of the aseptic method in the care of the newly born

Illustrative Case-record

Stillborn infant, aged 39 weeks The mother, a multipara aged 31, was admitted with toxæmia on Aug 5, 1959, at 37th week of pregnancy She was kept in bed, but her hypertension did not lessen and it was decided to induce labour by hind-water rupture of the membranes, this was done on Aug 14 The next day an oxytocin (' Pitocin ') drip was given which induced uterine contractions

The temperature rose to 105°F on the following day, with a rigor, tenderness was noted in the right loin and right iliac fossa A diagnosis of pyelitis of pregnancy was made, urine examination showed a few pus cells, and *Proteus vulgaris* was cultured A high vaginal swab produced a growth of *Staphylococcus pyogenes*, sensitive to most antibiotics, the organism was not present in the patient's nose Benzyl penicillin (penicillin G) 500,000 units and streptomycin 0 5 g were given twice daily On the same day, when the cervix was two finger breadths dilated, at approximately 1 30 P M , the fœtal heart sounds became inaudible

She was delivered at 3 45 P M on Aug 16 of a stillborn male fœtus weighing $5^1/_4$ lb (2410 g) Her temperature became normal next day, and recovery was uneventful

Necropsy

Tiny hæmorrhages were scattered over the visceral pleuræ of both lungs and over the visceral pericardium Small quantities of blood-stained fluid were seen in both pleural and pericardial cavities The spleen weighed 14 g , and appeared normal

No other abnormality was found The placenta and umbilical cord appeared normal macroscopically

Histological Findings

Lungs —All lobes of the lungs contained areas of intra-alveolar hæmorrhage, mingled with clusters of polymorphonuclear leucocytes and clumps of staphylococci There were numerous epithelial squames in alveoli and alveolar ducts A few veins contained thrombi

Placenta —Areas of purulent infiltration were seen in sections of placenta and umbilical cord

Bacteriological Investigations

The lungs and spleen were examined by the method described by Gresham and Gleeson-White (1957) All lobes grew a strain of *Staph pyogenes*, sensitive to all antibiotics against which it was tested (case 8, table III) The spleen was sterile

The findings in the other cases in this series are summarised in table I

Discussion

All infants showed histological evidence of pneumonia which varied from predominantly hæmorrhagic to frankly purulent infiltration In every case *Staph pyogenes* was isolated from the lungs

The histological appearances in the lungs could be classified broadly into three main groups

1 Extensive intra-alveolar hæmorrhage with necrosis of alveolar walls, together with abundant staphylococci Polymorphonuclear leucocytic infiltration was scanty This appears to represent an overwhelming infection—the organism being at the peak of its virulence and the host resistance low Two cases (1 and 6) fall into this group

2 Five showed the usual appearances of bacterial bronchopneumonia with sparse intrapulmonary hæmorrhage The duration of illness in these cases (3–7) was of the order of days rather than hours, as in the first group

3 One showed sparse polymorphonuclear leucocytic infiltration in alveoli (case 2) The staphylococcus was isolated both from the lung and from the spleen The changes in the lungs reflected those seen in other organs and were due to septicæmia

Five cases were infected with *Staph pyogenes* of the same antibiotic resistance patterns as those of the indigenous hospital staphylococcus This suggested that the source of infection was the hospital environment The route of infection in at least four of these was probably vaginal, three showed placentitis on histological examination In one (case 7) the infant was delivered at another hospital and the placenta was not available Nevertheless, the mother's vagina contained a *Staph pyogenes* similar in antibiotic resistance pattern to that isolated from the fœtal lung The finding of placentitis strongly supports the view that the bronchopneumonia in the fœtus was due to inhalation of infected amniotic fluid Further evidence

Analysis of the density curves is concerned with (1) the amplitude of the density variation in relation to the spirometer tracings, and (2) alterations in the time relationship between the two tracings

To illustrate these points two examples are described

Case 1 *Pulmonary emphysema with bullous emphysema of the right lower zone*—The spirometer tracings were similar during the examination of each of the four areas Normal respiration with a tidal flow of 1000–1200 ml of air was followed by a full inspiration (held for approximately 5 sec) and finally the forced expiration of approximately 2000 ml of air The forced expiration was considerably slower than in the normal subject (fig 6)

In the areas examined, the density tracings show considerable differences in amplitude and timing The left lower-zone tracing appears almost normal, following the spirometer curve closely The curve is synchronous with the spirometer tracing and the only abnormality is that, on forced expiration, the rate of loss of density is less than in the normal In the left upper-zone tracings, on forced expiration, there is a rapid initial loss of density, followed by a sudden check, and then a more gradual loss of density This contrasts with the smooth curve obtained from the lower zone The density tracing in the right upper zone is similar on forced expiration, but there is very little variation in lung density on normal respiration The density tracing in the right lower zone is grossly abnormal The density and spirometer curves are completely out of phase During respiration, the lung becomes more dense on inspiration and less dense on expiration On forced expiration, the lung initially becomes a little less dense and then shows no further change, even though the spirometer curve indicates that air is being expired from the lungs as a whole

Comment—The left lower zone is the area in which the tracings are nearest to normal There is the good synchronous variation in density with respiration, and an even loss of density on forced expiration This suggests that the most useful air movement is taking place in this area of the lung The upper zones, by comparison, show little variation in density on respiration On forced expiration, the sudden check in the density curve suggests that there is partial air-trapping after the start of expiration

The curves in the right lower zone are paradoxical, the density curve shows brightening on expiration The explanation for this is not known, but it may be due to air movement within the lungs, the air flowing into this region from other parts of the lungs

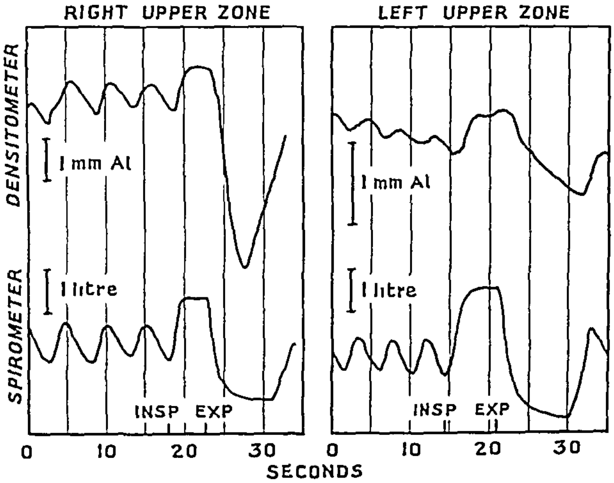

Fig 7—Case 2 Unilateral hypertranslucency of the left lung

The most important features are the smaller amplitude of density change on respiration and the slower rate of loss of density on forced expiration of the left upper zone compared with the right Since the densitometer sensitivity was greater when the left recording was made, the difference between the two sides is greater than appears at first sight

Case 2 *Radiological translucency of one lung*—A young man, without symptoms, was found, on routine X-ray examination, to have unilateral hypertranslucency of the left lung (Macleod 1954) The right pulmonary arteries appeared normal but the left pulmonary arteries appeared abnormally small Fluoroscopic examination showed that on expiration the left lung failed to deflate fully and the mediastinum swung to the right

The tracings obtained for the right and left upper zones are shown in fig 7 The spirometer tracings were similar when the two areas were examined The density and spirometer curves show synchronous movement But on normal respiration there is a much smaller amplitude of density change in the left upper zone when compared with the right On forced expiration, there is a much slower rate of loss of density in the left than in the right lung Similar changes were found in other zones It should be noted that the densitometer sensitivity was greater when recording the left side than when recording the right side (see scale fig 7), which means that the actual difference in density is greater than appears on the graphs

Comment—The small variation in lung density on normal respiration and the slow loss of density on forced expiration probably indicate that there is a much reduced air flow into and out of the left lung when compared with the right

Discussion

A number of factors, pulmonary and extrapulmonary, influence the overall radiolucency of the lung-fields during respiration The extrapulmonary factors are the ribs and soft tissues of the thoracic cage Their influence on the density curves is small On inspiration, the girth of the thoracic cage increases, thinning the overlying soft tissues and making them slightly more radiolucent This change is in phase with and slightly augments the overall pulmonary density curve The change in density caused by the ribs moving across the field during respiration is less regular than the soft-tissue effect By choosing a 5 cm diameter field, it is possible to even out the density changes produced by the ribs For example, the effect of the ribs and soft tissues over a pneumothorax, when no lung is in the field, is small compared with the changes in density over a normal lung field

The variation in radiolucency attributable to the pulmonary components are due to changes in blood contents and changes in air contents, the vascular component causes only a small ripple on the relatively large pulmonary density curve The main density changes are due to the air component

Sokolov (1956) has shown, by inflating the lungs of cadavers under experimental conditions, that the decrease in density which occurs with pulmonary inflation is dependent upon the total amount of lung tissue through which the X rays pass, and that this depends mainly on the amount of lung expansion which takes place in directions perpendicular to the rays Thus, in an anterior view of a lung, the decrease in density is influenced mainly by expansion in the vertical and transverse directions, in the coronal plane, and only little by expansion in the anteroposterior direction

The alterations of lung density during respiration, recorded by our densitometer, are a function of the degree of expansion of the part of lung under observation, and hence of the amount of air exchanged Since the observations are carried out under dynamic conditions, the curves give some indication of the air flow into and out of this part of the lung There is a recognisable normal pattern of tracings in different parts of the lung fields When there are abnormalities, correlation of the density tracings in the different areas with the spirometer tracings allows one to detect abnormalities of air flow When alterations in lung density occur without spirometer movement, intrapulmonary air flow must be taking place When there is localised air trapping, the densitometer tracing may show a slow rate of loss of density even though the spirometer tracings may be relatively normal Normally the densitometer and spirometer tracings are synchronous Asynchronous curves imply localised air-flow obstruction, or even reversal, as in one of our cases

The place of this radiological technique in the study of lung function has not yet been fully assessed It is hoped to correlate this method with other more conventional lung-function tests in order to establish its clinical value as a routine procedure

Summary

A radiological method of studying localised changes in lung density during respiration is described Simultaneous spirometer recordings are made

The curves obtained in normal and abnormal patients are described and analysed

The significance and interpretation of these findings is discussed

We wish to thank Mr C R. Brecknell for the figures, and Dr G C. Rivett for allowing us to carry out density studies on case 2

DIALYSIS DEPARTMENT, ST CLARA HOSPITAL, ROTTERDAM,
THE NETHERLANDS

In acute renal insufficiency patients not infrequently become overhydrated as water is liberated from the cells by catabolic processes Water is also formed by oxidation of body fat and dextrose To prevent overhydration the intake of water must be rigorously restricted (to 400–500 ml per day) during the anuric phase Overhydration may lead to pulmonary œdema and bronchopulmonary infection, and cerebral œdema sometimes causes convulsions, especially when too much sodium has been given in an attempt to correct acidosis

If progressive uræmia is complicated by severe overhydration, treatment with combined hæmodialysis and ultrafiltration is indicated Ultrafiltration occurs if the pressure in the extracorporeally circulating blood (i e, the colloid-osmotic pressure of the plasma) is at least 30 mm Hg higher than the pressure in the surrounding bath fluid, this is technically *feasible only if the filter* membrane (' Cellophane ') is supported by a rigid screen which prevents changes of the extracorporeal blood-volume Kolff's rotating kidney lacks this support, and therefore cannot be used as an ultrafiltrator Kolff's twin-coil kidney, however, is supported, in this type of kidney ultrafiltration is obligatory because the high inner resistance of the narrow cellophane coils demands a high perfusion pressure But the Skegg-Leonards and Alwall types of kidney seem preferable because they both give support to the cellophane membrane and allow controlled ultrafiltration

Method

In our department a modified Alwall dialyser has been used since 1952 Under standard conditions the patient loses no water As the inner resistance of the cellophane tubing spiral is low, a moderate perfusion pressure suffices for satisfactory flow This slight " over " pressure is partially compensated by the colloid-osmotic pressure and partially by the hydrostatic pressure of the bath fluid If the direction of flow through the cellophane spiral is from above downwards, the proximal coils will cause some ultrafiltration because the blood-pressure is high and the hydrostatic pressure of the bath fluid is low The distal coils will take up water from the bath because the perfusion pressure is low and the hydrostatic pressure of the bath is high In practice this maintains the water balance, as is shown by weighing the patient with a bed scale before, during, and after dialysis The bath fluid we use is not hypertonic to uræmic plasma

Ultrafiltration is made possible by placing an airtight lid on the bath-fluid reservoir, so creating a negative pressure in the air above the bath fluid The hydrostatic pressure in the bath will thus be lowered, and a pressure gradient will be established between bath fluid and blood This method has several disadvantages, including the high cost of airtight apparatus, the maintenance of a constant vacuum, and the sudden changes in blood-volume which arise during the rapid creation of a vacuum (although these changes are limited by the screen support, they may disturb the patient) A much simpler, cheaper, and easier way is to raise the pressure of the circulating blood This can be done by using a higher perfusion-rate, and by increasing the resistance in the circuit by constricting the outflow tube from the " kidney " to the

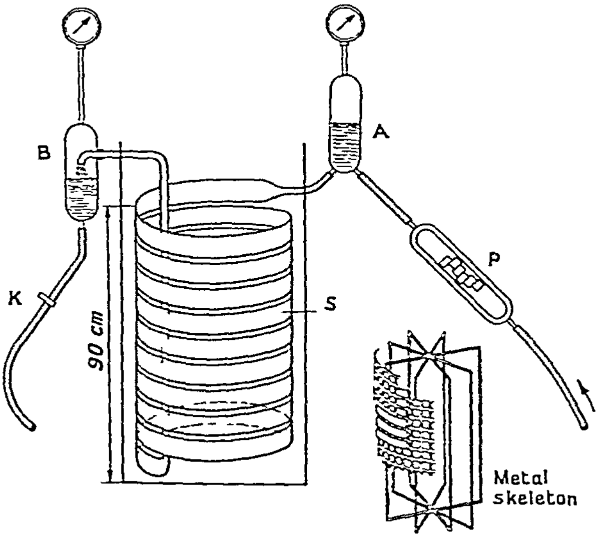

Fig 1—Schematic drawing of the Alwall kidney as ultrafiltrator
P=finger pump A and B=manometers respectively proximal and distal to the cellophane spiral, S K=adjustable screw

patient Fig 1 illustrates our technique, using a dialyser with 18 m of cellophane tubing

The perforated metal cylinders which form the screens for the cellophane spiral must be reinforced by a metal " skeleton " The inner cylinder would otherwise be damaged during operation by the considerable pressure resulting from application of positive pressure over a large surface Blood is pumped from the patient by a ' Sigma ' finger pump with adjustable speed (fig 1, P) The pump can be adjusted to ' occlusive " setting, which makes the rate of blood-flow relatively independent of the pressure head in A A is a simple manometer system which records the blood-pressure before it enters the proximal cellophane coils S is the cellophane spiral where ultrafiltration takes place This spiral is immersed in bath fluid B is a manometer system which records the blood-pressure as it leaves the distal coils The outflow tube can be narrowed by an adjustable screw, K, whereupon the pressure in B and in A will increase By using manometers A and B various pressure-flow relations can be recorded, this system also allows the blood flow-rate to be measured in vitro

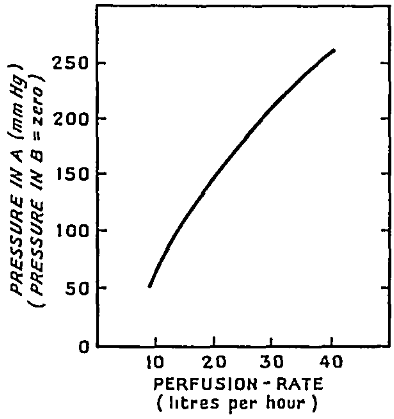

Fig 2—Pressure-flow relations in ultrafiltration with an 18 m cellophane tube, and without constriction of outflow tube

The pressure in A reaches 200 mm Hg at a perfusion-rate of 30 litres per hour

Fig 2 shows the increase in pressure in A when the rate of flow is increased without raising the pressure in B by creating a resistance at K As maximum safe pressure we have empirically chosen 200 mm Hg Above this pressure the inner cylinder may be damaged (even when reinforced) or the cellophane tube may leak 200 mm Hg pressure in A is achieved with a flow-rate of 30 litres per hour

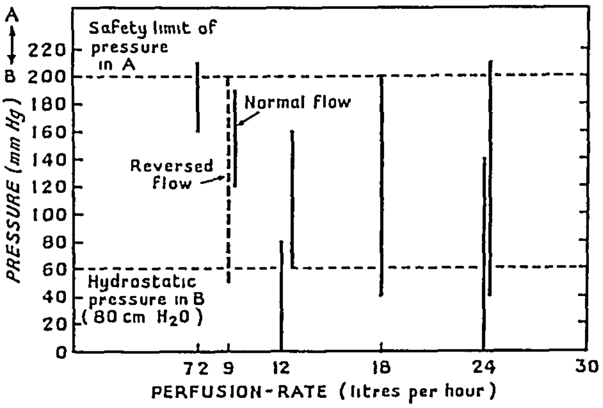

Fig 3—Pressure-flow relations with an 18 m cellophane ultrafiltrator

Pressure at B is variably increased Only moderate perfusion rates allow the pressure at B to increase considerably without excessive increase at A

Fig 3 shows the pressure-flow relations if the resistance at R is increased Each vertical column represents at the top the pressure in A, and at the bottom the pressure in B, at a certain flow-rate High flow-rates do not permit high pressures in B, because the pressure in A would then pass the safety limit Ultrafiltration will be most efficient, however, if it takes place along the whole length of the cellophane tubing, and for this a high pressure is necessary in B This can only be obtained with a moderate perfusion-rate Too low a rate is unfavourable because the blood becomes excessively dehydrated, and ultrafiltration is handicapped by increasing colloid-osmotic pressure A moderate flow of 10–12 litres per hour seems to be best for ultrafiltration If the direction of blood-flow is reversed (from below upwards) the pressure difference between A and B increases considerably because the hydrostatic pressure of the bath fluid has now to be overcome at A The resulting mean pressure $\frac{(A+B)}{2}$ is lower than with a normal flow, hence the direction of the blood-stream should be downwards

The efficiency of dialysis is greater if the flow-rate is increased (fig 4) High perfusion-rates (20–30 litres per hour) result in rapid clearances and consequently short dialyses If dialysis is combined with ultrafiltration, however, moderate flows of 10–12 litres per hour seem preferable

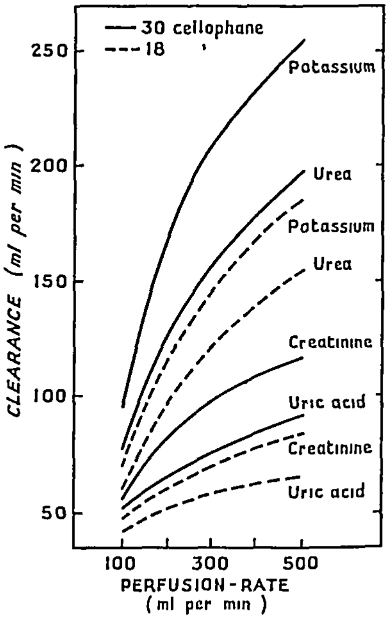

Fig 4—In-vitro clearances of the Alwall kidney at different perfusion-rates

We observed in vitro a water extraction of about 300 ml per hour—a figure which correlates well with our clinical experience and with other published data Higher rates of dehydration may lead to shock and hypotension The above rate was well tolerated by overhydrated patients, and it did not cause hypotension, although hypertension was sometimes reduced to normal

Summary

The artificial kidney of the Alwall type can be used for controlled ultrafiltration by creating a pressure difference between the extracorporeally circulating blood and the bath fluid

The optimal flow-rate for ultrafiltration is lower than that for dialysis

In clinical ultrafiltration water extraction of 300 ml per hour did not lead to hypotension if the patient was overhydrated

STAPHYLOCOCCAL PNEUMONIA IN THE NEONATAL PERIOD

THE DEPARTMENT OF PATHOLOGY, UNIVERSITY OF CAMBRIDGE

The pattern of tissue reaction to microbial infection varies with the virulence of the organism, the resistance of the host, and occasionally with the portal by which the organism gains access. Neonatal lung infection with the staphylococcus illustrates this point.

We describe here eight examples of staphylococcal pneumonia in the neonate which occurred during the period March, 1958, to August, 1959. They illustrate the often fulminant character of the infection and the variety of histological appearances in the lungs, and emphasise the need for the diligent use of the aseptic method in the care of the newly born.

Illustrative Case-record

Stillborn infant, aged 39 weeks. The mother, a multipara aged 31, was admitted with toxæmia on Aug. 5, 1959, at 37th week of pregnancy. She was kept in bed, but her hypertension did not lessen and it was decided to induce labour by hind-water rupture of the membranes; this was done on Aug. 14. The next day an oxytocin ('Pitocin') drip was given which induced uterine contractions.

The temperature rose to 105°F on the following day, with a rigor; tenderness was noted in the right loin and right iliac fossa. A diagnosis of pyelitis of pregnancy was made; urine examination showed a few pus cells, and *Proteus vulgaris* was cultured. A high vaginal swab produced a growth of *Staphylococcus pyogenes*, sensitive to most antibiotics; the organism was not present in the patient's nose. Benzyl penicillin (penicillin G) 500,000 units and streptomycin 0.5 g. were given twice daily. On the same day, when the cervix was two finger breadths dilated, at approximately 1.30 P.M., the fœtal heart sounds became inaudible.

She was delivered at 3.45 P.M. on Aug. 16 of a stillborn male fœtus weighing 5¹/₄ lb. (2410 g.). Her temperature became normal next day, and recovery was uneventful.

Necropsy

Tiny hæmorrhages were scattered over the visceral pleuræ of both lungs and over the visceral pericardium. Small quantities of blood-stained fluid were seen in both pleural and pericardial cavities. The spleen weighed 14 g., and appeared normal.

No other abnormality was found. The placenta and umbilical cord appeared normal macroscopically.

Histological Findings

Lungs.—All lobes of the lungs contained areas of intra-alveolar hæmorrhage, mingled with clusters of polymorphonuclear leucocytes and clumps of staphylococci. There were numerous epithelial squames in alveoli and alveolar ducts. A few veins contained thrombi.

Placenta.—Areas of purulent infiltration were seen in sections of placenta and umbilical cord.

Bacteriological Investigations

The lungs and spleen were examined by the method described by Gresham and Gleeson-White (1957). All lobes grew a strain of *Staph. pyogenes*, sensitive to all antibiotics against which it was tested (case 8, table III). The spleen was sterile.

The findings in the other cases in this series are summarised in table I.

Discussion

All infants showed histological evidence of pneumonia which varied from predominantly hæmorrhagic to frankly purulent infiltration. In every case *Staph. pyogenes* was isolated from the lungs.

The histological appearances in the lungs could be classified broadly into three main groups:

1. Extensive intra-alveolar hæmorrhage with necrosis of alveolar walls, together with abundant staphylococci. Polymorphonuclear leucocytic infiltration was scanty. This appears to represent an overwhelming infection—the organism being at the peak of its virulence and the host resistance low. Two cases (1 and 6) fall into this group.

2. Five showed the usual appearances of bacterial bronchopneumonia with sparse intrapulmonary hæmorrhage. The duration of illness in these cases (3–7) was of the order of days rather than hours, as in the first group.

3. One showed sparse polymorphonuclear leucocytic infiltration in alveoli (case 2). The staphylococcus was isolated both from the lung and from the spleen. The changes in the lungs reflected those seen in other organs and were due to septicæmia.

Five cases were infected with *Staph. pyogenes* of the same antibiotic resistance patterns as those of the indigenous hospital staphylococcus. This suggested that the source of infection was the hospital environment. The route of infection in at least four of these was probably vaginal; three showed placentitis on histological examination. In one (case 7) the infant was delivered at another hospital and the placenta was not available. Nevertheless, the mother's vagina contained a *Staph. pyogenes* similar in antibiotic resistance pattern to that isolated from the fœtal lung. The finding of placentitis strongly supports the view that the bronchopneumonia in the fœtus was due to inhalation of infected amniotic fluid. Further evidence

S=sensitive R=resistant

for the view that inhalation was the route of pneumonic infection is provided by the occurrence of fœtal distress, and the presence of numerous amniotic squames in the air-passages of all infants in which this route is postulated A vaginal route of infection is also supported by the fact that an undue number of vaginal procedures were made in the antenatal period, these were carried out because of a high incidence of antenatal complications in these mothers (table I)

The sensitivity of the organisms to various antibiotics is shown in table III Three strains were sensitive to all the antibiotics against which they were tested These three organisms were probably derived from the mothers themselves, or from a newly introduced strain carried into the ward Case 8 (table I) is typical, a high vaginal swab from the mother before delivery showed a sensitive strain of *Staph pyogenes*

In three cases the mother's vagina did not grow *Staph pyogenes* though it was isolated from the fœtal lungs However, the interval of several days between delivery and taking a vaginal swab may explain this discrepancy

Cases 4 and 5 (table I) were infants with congenital abnormalities They survived much longer than all other infants in this series The organism responsible for their pneumonia had the same resistance pattern as the indigenous hospital staphylococcus They were probably infected post partum There were no inflammatory changes of the umbilical cord or placenta in case 4 The other placenta was not available

Three cases showed œsophagitis, associated with intubation and the administration of gastric oxygen The lesion was probably incidental, and was not the primary source of infection

All infants were premature as judged by weight The number of ossification centres found at necropsy varied from case to case (table III) Most were found in case 5—an infant with multiple congenital abnormalities This suggests that such babies may be expected to develop lung infections, either because prematurity reflects antenatal complications and the need for excessive manipulations, or because they are unduly susceptible to infection

Summary

Eight cases of fatal staphylococcal pneumonia in neonates are described The infection was often fulminant, and a variety of histological appearances—ranging from extensive intra-alveolar hæmorrhage with necrosis of the alveolar walls to a slight polymorphonuclear leucocytic infiltration—were found post mortem

The causal organism in every case was *Staphylococcus pyogenes* It is suggested that in six of the infants the bronchopneumonia was due to the inhalation of infected amniotic fluid, two cases were probably infected post partum The need for diligent application of aseptic methods in the care of the newly born is stressed

Our thanks are due to Dr A M Barrett, Dr D M T Gairdner, and Dr M H Gleeson-White for their cooperation in the preparation of this paper

GONADAL DYSGENESIS (TURNER'S SYNDROME) WITH MALE PHENOTYPE AND XO CHROMOSOMAL CONSTITUTION

From the Department of Endocrinology and Metabolic Disorders, Faculty of Medicine, São Paulo, and the Department of Clinical Medicine, Faculty of Medicine, Ribeirão Preto, Brazil

A boy, aged 8, the eldest son of young parents, was admitted to the metabolic department on April 5, 1957, because of poor somatic development.

Maternal pregnancy and labour had been normal. General condition was fair. Height 3 ft. 9 in. (113 cm.), weight 45 4 lb (20·6 kg.), span 3 ft. 7 in. (110 cm.) (fig 1). Clinical examination revealed malformed external genitalia and some lesser congenital defects—low hair-line and ears, high-arched palate, and a number of naevi. The penis 1 2 in. (3 1 cm.) long, without urethral meatus, was bent ventrally by a web connecting the ventral surface to the perineum. Thus the "scrotum" appeared to be bifid, a depression with two small meatuses being visible in the midline, one communicated with the bladder through a short urethra, and the other led to a closed cavity (fig 2). When the patient underwent plastic surgery, it was verified this cavity communicated with the uterus. No testes could be felt in the labioscrotal folds or in the inguinal regions. A rudimentary uterus was seen on peritoneoscopy and a laparotomy was done for further investigation of the internal genitalia. Near the small left tube was an elongated, almond-shaped mass ³⁄₈ in. (1 cm.) long, which was histologically a rudimentary testis (figs. 3 and 4). On the right, instead of an ovary, there was connective tissue, as seen in other cases of gonadal dysgenesis with negative chromatin pattern (Epps et al. 1958). 17-ketosteroids (Drekter) 0·8 mg. per 24 hours. Bone age of 7 years, X-ray examination of the skull, no abnormality. Colour-vision normal (Ishihara tests).

The nuclear sex in material obtained from the blood, oral smears, and from the skin biopsy was male. In the blood-smears, no "drumsticks" were found in 500 leucocytes counted. Chromosomal counts (Bottura and Ferrari 1960) in the 20 bone-marrow specimens examined gave a constant number of 45 chromosomes. In the 13 cells in optimal condition, 4 small acrocentric chromosomes could be positively identified. After pairing (fig 5), the absence of a second medium-sized chromosome with subcentral centromere (probably an X chromosome) was noted. In view of these facts, the chromosomal constitution of the patient must be XO. The constancy of the number 45 in the chromosomal counts argues against

the possibility of mosaicism as far as bone-marrow cells are concerned

Discussion

XO chromosomal constitution in gonadal dysgenesis with female phenotype was described by Ford et al (1959) A reasonable assumption from the study of our case is that XO chromosomal constitution is not incompatible with a male phenotype and with the presence of embryonic testis Further instances of testicular development with a male phenotype without Y chromosome are represented by the XX true hermaphrodites recently reported (Harnden and Armstrong 1959, Hungerford et al 1959, de Assis et al 1960, Ferguson-Smith et al 1960)

Summary

We describe a case of gonadal dysgenesis (Turner's syndrome) in a boy of 8 He had a rudimentary uterus, and an embryonic testis No ovaries were found The nuclear sex was male "Drumsticks" were absent from the leucocytes Only 45 chromosomes were present in the cells of all (20) bone-marrow specimens examined, and chromosome analysis pointed to the absence of one X chromosome His phenotype is, therefore, male with an XO chromosomal constitution

PREMEDICATION WITH ATROPINE BY MOUTH

M C JOSEPH
M D Cantab , M R C P , D C H
ASSISTANT TO THE DIRECTOR OF THE DEPARTMENT OF CHILD HEALTH

R J VALE
M B Lond , M R C P E , F F A R C S
CONSULTANT ANÆSTHETIST

GUY'S HOSPITAL, LONDON, S E 1

IN 1872 Heidenhain demonstrated that the salivary secretion produced by stimulation of the chorda tympani was prevented by atropine, and, in the next year, Ebstein used it therapeutically in a patient with apoplexy In 1875 Munro reported its use in cats for preventing early cardiac arrest during chloroform anæsthesia, but it was not until after 1890 that the subcutaneous injection of atropine before induction of anæsthesia came into general use in this country

There seems to be no record of the oral administration of atropine before operation, though it is used therapeutically for various conditions Even when sedative drugs are given by mouth preoperatively, it has still been common practice to inject atropine, though Dr W S McConnell tells us he has used it by mouth effectively In children it is especially desirable to avoid injections, hence we conducted this trial of the effect of atropine given by mouth

The Trial

All children admitted to the Evelina Hospital, under the same surgeon and anæsthetist for tonsillectomy, were included in the trial When admitted, the day before the operation, the child was placed in an "oral" or "subcutaneous" group by random allocation, the anæsthetist being unaware of the grouping The trial lasted fifteen months, and ended when the anæsthetist ceased to work at this hospital

240 children were admitted to the trial, but 93 were excluded because a different anæsthetist was working on that occasion or because the data were incomplete There remained 147 children for study Their sex, average weights, and ages were

	No	*Males*	*Females*	*Age (yr)*	*Weight (lb)*
Oral	74	41	33	6 5	49
Subcutaneous	73	39	34	6 7	51

and the age-distribution was

	No	*3–5 yr*	*6–8 yr*	*9–12 yr*
Oral	74	21	44	9
Subcutaneous	73	17	45	11

The average interval between administration of atropine and induction of anæsthesia was 95 and 87 minutes for the oral and subcutaneous groups respectively

During the night before operation the sleeping pulse was measured twice Next morning, an hour before the expected time of operation, atropine was given—either 0 85 mg by mouth or 0 64 mg subcutaneously—with butobarbitone, in a dose of 75 mg per stone body-weight The pulse-rate was recorded again just before the child was taken to the operating-theatre, and the state of consciousness was noted In the anæsthetic-room the size of the pupils was measured to the nearest millimetre by comparison with a prepared scale, and the reaction to light was noted All patients were anæsthetised with ether after induction with either ethyl chloride on a Schimmelbusch mask or nitrous oxide and oxygen through a semiopen circuit The degree of salivation was assessed during induction by inserting a finger into the buccal sulcus, if it was dry or slightly moist, it was recorded as O, if wet but not dripping off the finger as +, and if copious and stringy as ++ Additionally, if salivation interfered with induction, it was recorded as ++

Results

Salivation

The degree of salivation was

	No	*O*	*+*	*++*
Oral	74	63	9	2
Subcutaneous	73	68	4	1

Excessive salivation was uncommon in either group, occurring only twice in the oral group and once in the subcutaneous group There was a little more mild salivation in the oral group than in the subcutaneous group, but the difference was small and not significant at the 5% level

Pupils

The average size of the pupils was identical in the two groups, and the incidence of negative reaction to light was similar

	No	*Size (mm)*	*Negative reaction*
Oral	74	6 1	15 (*19%*)
Subcutaneous	73	6 1	11 (*15%*)

Pulse-rate

The response of the pulse-rate was

	No	*Before atropine*	*After atropine*	*Rise*
Oral	74	85	107	22
Subcutaneous	73	86	111	25

The mean rate before atropine was similar in both groups, there being a rise of 22 and 25 beats per minute in the oral and subcutaneous groups respectively

Discussion

Dose

Unna et al (1950) have shown that the smallest effective dose of atropine for suppression of salivation in children aged 3–12 years is about 0 007 mg per kg body-weight subcutaneously, or three times this dose by mouth The dose for a 20 kg child is about a quarter the dose of

0 64 mg commonly used subcutaneously Mushin and Galloon (1953) also regard 0 64 mg subcutaneously as more than is needed to suppress salivation Thus our subcutaneous dose was probably three times larger than necessary, and our oral dose was the smallest effective dose recommended by Unna et al

Salivation

Although we evaluated the effect of atropine by several criteria, the suppression of salivation is especially important in premedication, and is also the most sensitive index of the effect of atropine (Unna et al 1950) Our finding of excessive salivation in 2% was similar to the 4% observed by Marx and Orkin (1959), but their figures were for atropine and scopolamine, and they pointed out that their atropine group had more secretion than their scopolamine group

During our study atropine was deliberately not given to a few patients, in order to establish that it had some effect But the excessive salivation and extreme bradycardia in the first five children so treated made us unwilling to continue, and we resumed the trial Mushin and Galloon (1953) pointed out that the degree of salivary depression necessary depended on the type of anæsthesia used, ether needing about 40% and nitrous oxide about 10% depression We used ether, and therefore our patients needed maximum depression of salivation

Pupils and Pulse-rate

Both mydriasis and tachycardia are unreliable signs of the effect of atropine, because anxiety, excitement, or barbiturates may also produce these signs, but atropine was probably responsible for mydriasis in some of our patients, as the correlation between size of pupil and reaction to light was significant

	No	*Size of pupil (mm) with positive reaction*	*No*	*Size of pupil (mm) with negative reaction*
Oral	59	5 7±0 19	15	7 8±0 82
Subcutaneous	62	5 8±0 19	11	8 1±0 96

Difference in size of pupils is significant ($P = <0\ 05 > 0\ 02$)

We cannot be sure that the rise of pulse-rate was solely due to atropine, although it probably made a substantial contribution. The rise in pulse-rate was similar in both our groups

We were unable to show any correlation between pupil size, rise in pulse-rate, and salivation However, we found correlation between the size of pupil and its response to light, the fixed pupils having a mean diameter of 7 8 and 8 1 mm (oral and subcutaneous) compared with 5 7 and 5 8 mm for the active pupils It is interesting that we found this correlation in the oral group, for Unna et al (1950) pointed out that the smallest dose by mouth which suppressed salivation did not cause mydriasis or tachycardia

The average time between giving atropine and inducing anæsthesia was 95 and 87 minutes in the two groups This interval is similar to that observed by Unna et al (1950), who found the greatest effect of atropine was between sixty and a hundred and twenty minutes for an oral group, and to that of Mushin and Galloon (1953), who found the greatest effect between sixty and ninety minutes for a subcutaneous group

Our investigation has shown that, in children, atropine given by mouth is as effective as atropine given by subcutaneous injection As it is desirable to avoid injection in children, the oral route seems preferable

Summary

147 children randomly selected were given oral or subcutaneous atropine before anæsthesia, and the effects on salivation, pupils, pulse-rate, and anæsthesia were observed No differences between the groups were found

Thus is it concluded that atropine by mouth is satisfactory for premedication

We wish to thank the nursing staff and residents at the Evelina Children's Hospital for their help, and Mr L F W Salmon for allowing us to conduct this trial on patients under his care

Preliminary Communications

ANTINUCLEAR FACTORS IN THE SERUM OF RELATIVES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

DURING an investigation of antinuclear factors in the serum of patients with systemic lupus erythematosus (S L E) we found a relationship between the titre of antinuclear factors in the serum and the clinical activity of the disease High titres were found in patients with active S L E , the titres were considerably lower in most patients in whom the disease was adequately controlled by treatment with prednisone [1] As this test for antinuclear factors was sensitive, and as the results could be quantitated, we were prompted to examine the serum of relatives of patients with S L E for antinuclear factors, particularly in view of recent reports of the familial occurrence of S L E [2–8]

MATERIAL AND METHODS

Smears of fresh unfixed healthy human buccal mucosal epithelial cells were used as the source of the cell nuclei After washing with 0 01 *M* saline phosphate buffer (pH 7 0) the slides were air-dried, and the smears were covered with a drop of the test serum The smears were incubated for 90 minutes at room temperature in a moist atmosphere The slides were washed for 30 minutes in three changes of buffer, air-dried, and layered for 30 minutes with rabbit antihuman γ-globulin conjugated with fluorescein isothiocyanate (Sylvana) They were washed and were then mounted in buffered glycerin They were inspected for specific nuclear fluorescence, using a Reichert Zetopan microscope with an aplanatic dark field condensor (light source Osram HBO 200 mercury-vapour lamp, Corning 5840 and Wratten 2A filters)

All tests were done in duplicate When specific nuclear fluorescence was found, serial dilutions of serum (to 1 4096) were incubated with smears of buccal mucosal cells in a similar fashion The highest dilution in which specific nuclear fluorescence was detected was called the ' titre " of antinuclear factors

Full details of the technique and controls used will be published elsewhere [1] It was shown that duplicate titrations on the same sera gave identical titres in 4 of 10 instances The final titres differed by only one dilution in the other 6

RESULTS

The results are shown in table I Single serum samples from 40 healthy subjects and 50 sera from 45 patients with

TABLE I—TITRES OF ANTINUCLEAR FACTORS IN HEALTHY SUBJECTS, IN PATIENTS WITH VARIOUS DISEASES UNRELATED TO S L E, AND IN PATIENTS WITH S L E AND THEIR RELATIVES

Titre of Antinuclear factors (dilution)	Healthy subjects	Diseases unrelated to S L E	Patients with S L E	Relatives of patients with S L E
Negative				
Undiluted	33	40	3	20
1 1	3	5	2	3
1 2	4	4	1	3
Positive				
1 4 to 1 16	0	1	12	17
1 32 to 1 128	0	0	14	4
1 256 to 1 4096	0	0	19	3

diseases unrelated to S L E were studied as controls Specific nuclear fluorescence was not seen with 73 of these sera, and was seen with undiluted serum or serum diluted 1 2 in another 16 sera In only 1 instance was specific nuclear fluorescence seen when the serum was diluted 1 4

51 patients with S L E were studied When the first serum drawn from each of these patients was examined, specific nuclear fluorescence was found with serum diluted 1 4 or higher in 45 In all, 151 specimens of serum from these 51 patients have been examined to date, and specific nuclear fluorescence with serum diluted 1 4 or higher was observed with 131 specimens As antinuclear factors were found when the serum was diluted 1 4 in only 1 of 90 sera examined as controls, the demonstration of antinuclear factors in serum diluted 1 4 or more appeared to distinguish patients with S L E from healthy subjects and those with a variety of other diseases The test was therefore called positive when antinuclear factors were demonstrated in serum diluted 1 4 or more

TABLE II—RESULTS OF TESTS FOR ANTINUCLEAR FACTORS IN THE RELATIVES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHMATOSUS

Relationship	Female relatives		Male relatives	
	Positive tests	Negative tests	Positive tests	Negative tests
Parents	5	1	0	4
Siblings	6	4	4	5
Offspring	2	0	2	3
Maternal siblings	3	1	1	1
First cousins	1	0	0	1
Grandparents	0	3	0	3
Totals	17	9	7	17

Single serum samples from 50 members of families of 12 patients with S L E were studied (tables I and II) Specific nuclear fluorescence was demonstrated with serum diluted 1 4 or more in 24 instances Positive tests were found with the sera of 19 of 36 first-degree relatives tested, and with the sera of 5 of 14 second-degree relatives Positive tests were found in 17 of 26 female relatives but in only 7 of 24 male relatives The difference in the frequency of positive tests in male and female relatives is significant (χ^2=5 2, P= <0 05), but further observations on this difference are necessary

Two family pedigrees are shown in fig

In the first pedigree the propositus (II 4) a 15-year-old schoolgirl in whom defin clinical evidence of S L E had been found, an in the past, Hargraves' cells had been demonstrated in her blood Findings diagnostic o lupus nephritis were observed in a renal biops 4 specimens of serum were tested for antinuclear factors when the patient was symptom-free as a result of treatment with prednisone, all were negative Positive tests for antinuclear factors were found in the mother (I 1) and 3 of 5 siblings—in 1 of whom (II 1) the titre was 1 1024

In the second pedigree the propositus (II 2) was a 21-year-old American Negro housewife with typical S L E Positive tests for antinuclear factors were found in the serum of the patient, her 2 younger sisters, her 5-year-old son, and 3-year-old daughter (III 3)—in whom the titre of antinuclear factors was 1 4096

The serum-γ-globulin levels were estimated by the Biuret reagent and filterpaper electrophoresis They are compared in fig 2 with values from 62 healthy Caucasian (1 13±0 23 g per 100 ml) and 62 healthy American Negro subjects (1 37±0 30 g per 100 ml) Elevated γ-globulin levels (>2 S D above the mean of the controls) were found in only 3 Caucasian relatives and 2 Caucasian controls Decreased γ-globulin levels (>2 S D below the *mean of the controls) were found in* 1 Caucasian *and* 2 Negro relatives 5 of the 6 Negro relatives were members of one family (pedigree 2) The difference between the γ-globulin levels in the members of this family and those in the controls was significant (χ^2=17 2, P= <0 01)

DISCUSSION

In 1957 Leonhardt [2] reported S L E in 3 of 14 siblings He pointed out that at that time there were only four reported instances of the familial occurrence of S L E

Subsequently, Agranat et al [3] Larsson and Leonhardt,[4] and Lawrence [5] have each reported S L E in 2 sisters Wagenhals and Burgeson [6] observed the disease in twin sisters Griffin et al [7] found S L E in a father and his daughter, and Holman and Deicher [8] reported its occurrence in a mother and her daughter These clinical observations suggested that S L E may possibly be a familial disorder

In a study of two pedigrees, Larsson and Leonhardt [4] found higher mean serum-γ-globulin levels in siblings of patients with S L E and their children than in controls living under the same environmental conditions The siblings had higher mean γ-globulin values than the first cousins, and the siblings' children than the second cousins Larsson and Leonhardt considered that familial hypergammaglobulinæmia and familial S L E were possibly closely related and were manifestations of an underlying, genetically determined tendency to overproduction of γ-globulin Holman and Deicher [8] found "distinct hypergammaglobulinæmia" in 11 of 57 relatives from 18 families of patients with S L E, and Rodnan et al [9] found definite hypergammaglobulinæmia in 12 of 59 relatives, thus confirming the observations of Larsson and Leonhardt

DISCUSSION

In 1957 Leonhardt[2] reported S L E in 3 of 14 siblings He pointed out that at that time there were only four reported instances of the familial occurrence of S L E

Subsequently, Agranat et al[3] Larsson and Leonhardt,[4] and Lawrence[5] have each reported S L E in 2 sisters Wagenhals and Burgeson[6] observed the disease in twin sisters Griffin et al[7] found S L E in a father and his daughter, and Holman and Deicher[8] reported its occurrence in a mother and her daughter These clinical observations suggested that S L E may possibly be a familial disorder

In a study of two pedigrees, Larsson and Leonhardt[4] found higher mean serum-γ-globulin levels in siblings of patients with S L E and their children than in controls living under the same environmental conditions The siblings had higher mean γ-globulin values than the first cousins, and the siblings' children than the second cousins Larsson and Leonhardt considered that familial hypergammaglobulinæmia and familial S L E were possibly closely related and were manifestations of an underlying, genetically determined tendency to over-production of γ-globulin Holman and Deicher[8] found "distinct hypergammaglobulinæmia" in 11 of 57 relatives from 18 families of patients with S L E, and Rodnan et al[9] found definite hypergammaglobulinæmia in 12 of 59 relatives, thus confirming the observations of Larsson and Leonhardt

BLOOD-GROUP DISTRIBUTION IN MEGALOBLASTIC ANÆMIA OF PREGNANCY

FOLIC-ACID deficiency in pregnancy is characterised by the appearance of megaloblasts in the marrow In the most severe cases these are of the classical Ehrlich type, as seen in addisonian anæmia, whereas transitional megaloblasts are encountered in the milder forms of the disease More recent studies have shown that folic-acid depletion frequently occurs in late pregnancy without producing megaloblastic changes in the marrow,[13] although the hæmoglobin-level can generally be raised by the administration of folic acid [14]

Folic-acid deficiency in pregnancy can thus be conveniently classified in four categories

Grade 0—The marrow remains entirely normoblastic and folic-acid depletion can be diagnosed with certainty only by folic-acid assays In these cases the hæmoglobin level can usually be raised by folic-acid therapy

Grade 1—The mildest form of megaloblastic anæmia, in which the marrow is predominantly normoblastic, though it contains a number of transitional megaloblasts Diagnosis in such cases may need confirmation by other criteria—e g, a raised serum-iron level and satisfactory response to folic-acid therapy

Grade 2—The marrow is predominantly megaloblastic, but the majority of cells is of the transitional type.

Grade 3—A florid megaloblastic marrow in which the classical Ehrlich type of megaloblast predominates The marrow picture in these cases is indistinguishable from that seen in addisonian anæmia

Obviously, the marrow-changes in these four categories reflect, to some extent, the degree of folic-acid depletion in any given person It would be an oversimplification to assume from this that all pregnant women with folic-acid

TABLE I—TITRES OF ANTINUCLEAR FACTORS IN HEALTHY SUBJECTS, IN PATIENTS WITH VARIOUS DISEASES UNRELATED TO S L E, AND IN PATIENTS WITH S L E AND THEIR RELATIVES

Titre of Antinuclear factors (dilution)	Healthy subjects	Diseases unrelated to S L E	Patients with S L E	Relatives of patients with S L E
Negative				
Undiluted	33	40	3	20
1 1	3	5	2	3
1 2	4	4	1	3
Positive				
1 4 to 1 16	0	1	12	17
1 32 to 1 128	0	0	14	4
1 256 to 1 4096	*0*	*0*	*19*	*3*

diseases unrelated to S L E were studied as controls Specific nuclear fluorescence was not seen with 73 of these sera, and was seen with undiluted serum or serum diluted 1 2 in another 16 sera In only 1 instance was specific nuclear fluorescence seen when the serum was diluted 1 4

51 patients with S L E were studied When the first serum drawn from each of these patients was examined, specific nuclear fluorescence was found with serum diluted 1 4 or higher in 45 In all, 151 specimens of serum from these 51 patients have been examined to date, and *specific nuclear fluorescence with serum diluted 1 4* or higher was observed with 131 specimens As antinuclear factors were found when the serum was diluted 1 4 in only 1 of 90 sera examined as controls, the demonstration of antinuclear factors in serum diluted 1 4 or more appeared to distinguish patients with S L E from healthy subjects and those with a variety of other diseases The test was therefore called positive when antinuclear factors were demonstrated in serum diluted 1 4 or more

TABLE II—RESULTS OF TESTS FOR ANTINUCLEAR FACTORS IN THE RELATIVES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHMATOSUS

Relationship	Female relatives		Male relatives	
	Positive tests	Negative tests	Positive tests	Negative tests
Parents	5	1	0	4
Siblings	6	4	4	5
Offspring	2	0	2	3
Maternal siblings	3	1	1	1
First cousins	1	0	0	1
Grandparents	0	3	0	3
Totals	17	9	7	17

Single serum samples from 50 members of families of 12 patients with S L E were studied (tables I and II) Specific nuclear fluorescence was demonstrated with serum diluted 1 4 or more in 24 instances Positive tests were found with the sera of 19 of 36 first-degree relatives tested, and with the sera of 5 of 14 second-degree relatives Positive tests were found in 17 of 26 female relatives but in only 7 of 24 male relatives The difference in the frequency of positive tests in male and female relatives is significant (χ^2=5 2, P= <0 05), but further observations on this sex difference are necessary

Two family pedigrees are shown in fig 1

In the first pedigree the propositus (II 4) was a 15-year-old schoolgirl in whom definite clinical evidence of S L E had been found, and, in the past, Hargraves cells had been demonstrated in her blood Findings diagnostic of lupus nephritis were observed in a renal biopsy nuclear factors when the patient was symptom-free as a result of treatment with prednisone, all were negative Positive tests for antinuclear factors were found in the mother (I 1) and 3 of 5 siblings—in 1 of whom (II 1) the titre was 1 1024

In the second pedigree the propositus (II 2) was a 21-year-old American Negro housewife with typical S L E Positive tests for antinuclear factors were found in the serum of the patient, her 2 younger sisters, her 5-year-old son, and 3-year-old daughter (III 3)—in whom the titre of antinuclear factors was 1 4096

The serum-γ-globulin levels were estimated by the Biuret reagent and filterpaper electrophoresis They are compared in fig 2 with values from 62 healthy Caucasian (1 13±0 23 g per 100 ml) and 62 healthy American Negro subjects (1 37±0 30 g per 100 ml) Elevated γ-globulin levels (>2 S D above the mean of the controls) were found in only 3 Caucasian relatives and 2 Caucasian controls Decreased γ-globulin levels (>2 S D below the mean of the controls) were found in 1 Caucasian and 2 Negro relatives 5 of the 6 Negro relatives were members of one family (pedigree 2) The difference between the γ-globulin levels in the members of this family and those in the controls was significant (χ^2=17 2, P= <0 01)

DISCUSSION

In 1957 Leonhardt [2] reported S L E in 3 of 14 siblings He pointed out that at that time there were only four reported instances of the familial occurrence of S L E

Subsequently, Agranat et al [3] Larsson and Leonhardt,[4] and Lawrence [5] have each reported S L E in 2 sisters Wagenhals and Burgeson [6] observed the disease in twin sisters Griffin et al [7] found S L E in a father and his daughter, and Holman and Deicher [8] reported its occurrence in a mother and her daughter These clinical observations suggested that S L E may possibly be a familial disorder

In a study of two pedigrees, Larsson and Leonhardt [4] found higher mean serum-γ-globulin levels in siblings of patients with S L E and their children than in controls living under the same environmental conditions The siblings had higher mean γ-globulin values than the first cousins, and the siblings' children than the second cousins Larsson and Leonhardt considered that familial hypergammaglobulinæmia and familial S L E were possibly closely related and were manifestations of an underlying, genetically determined tendency to over-production of γ-globulin Holman and Deicher [8] found "distinct hypergammaglobulinæmia" in 11 of 57 relatives from 18 families of patients with S L E, and Rodnan et al [9] found definite hypergammaglobulinæmia in 12 of 59 relatives, thus confirming the observations of Larsson ahd Leonhardt

The mean values are given by continuous lines and two standard deviations by interrupted lines.

○ = patients with positive tests for antinuclear factors
● = patients with negative tests for antinuclear factors

We found few relatives with hypergammaglobulinæmia, but somewhat high γ-globulin levels were found in 5 of 7 members of pedigree 1. Unusually low γ-globulin levels were found in 4 of 5 members of pedigree 2. This finding is of interest in view of the reported development of an arthritis resembling rheumatoid arthritis in almost half of 16 children with the congenital form of agammaglobulinæmia, and of collagen disease in patients with congenital and acquired agammaglobulinæmia.[10]

The most striking abnormality found was the high prevalence of positive tests for antinuclear factors in the serum of relatives of patients with S.L.E. The results strongly suggest that an abnormal protein or proteins with an affinity for cell nuclei in vitro are present in the serum of about half the relatives. By contrast, positive tests for antinuclear factors were found in the serum of only 1 of 50 subjects with diseases unrelated to S.L.E. and in none of the 40 healthy subjects studied. Hargraves' cells have been reported in about 12% of patients with rheumatoid arthritis[11] and occasionally in other so-called collagen diseases. We found positive tests for antinuclear factors in the serum of only 5 of 35 patients with these disorders. Thus the prevalence of positive tests for antinuclear factors was considerably higher in relatives of patients with S.L.E. than in patients with rheumatoid arthritis, scleroderma, and dermatomyositis. As rheumatoid arthritis and positive serological tests for rheumatoid factor appear to be commoner in relatives of patients with S.L.E. that in the general population,[8] [9] relatives of patients with S.L.E. may possibly comprise at least a proportion of the patients with clinical rheumatoid arthritis and positive Hargraves' cells or antinuclear factors.

The ætiology of systemic lupus erythematosus is still unknown. In recent years abundant evidence has been accumulated that the serum of patients with S.L.E. contains several abnormal γ-globulins. These abnormal γ-globulins, which react with cells or cell constituents in vitro, can probably be classified as auto-immune antibodies. Patients with S.L.E. also show increased responsiveness to foreign antigens.[12] The mechanism underlying the appearance of autoimmune antibodies and the increased sensitivity to foreign antigens is still poorly understood. Both these abnormalities, however, point to a derangement in the system regulating "immunological homœstasis." The data reported here indicate that this derangement probably has an hereditary basis, and suggest that overt disease may result from exposure to various antigens and other provocative stimuli in persons with the appropriate hereditary abnormality in the homœstasis of the antibody-producing system.

We wish to thank Mrs. Anne Doig, Mrs. Janet Rezaian, and Mr. Marcellus Moore for technical assistance. This study was supported in part by a grant (H2253) from the United States Public Health Service, National Institutes of Health, Bethesda, Maryland.

Cooling and rewarming is by means of a heat-exchanger constructed from stainless steel. A filter and bubble trap are incorporated in the arterial outflow line. Two sucker lines are provided which deliver their blood on to five perforated plates lightly coated with anti-foam. The output of the arterial pump and of the pump controlling the suction lines can be varied by two simple hand controls. The apparatus and tubing in contact with blood is sterilised in ethylene oxide for 24 hours before use.

The hypothermic and heating equipment is contained within a low trolley which acts as a mount for the heart-lung machine. In this way the apparatus, while remaining compact, is entirely self-contained. The cold source is supplied with a mixture of ice and water kept in a lagged 2 gal. tank, and hot water is kept thermostatically controlled at about 40°C in a separate tank.

Application

The apparatus has been used in twenty-five dog experiments. In addition, four children have been operated on, with one death. In use the machine requires very little adjustment, the running being in the hands of one technician.

The apparatus has been constructed for me by Mr. A. F. Turner in the Guy's Hospital Medical School workshop, and it will be available through Cardiac Recorders, Ltd., Weymouth Street, London, W.1.

Reviews of Books

Medical and Dental Aspects of Fluoridation

W. A. CANNELL, M.R.C.S., D.P.H., L.D.S. London: Lewis. 1960. Pp. 125. 15s.

MOST of the growing literature of fluoridation and fluorine is scattered in various journals. A great deal of the research has been done in the United States, and the few books that have appeared since Roholm's classic text in 1937 have been published there. A British survey of the present state of knowledge is welcome, and Dr. Cannell gives a concise and readable summary, with an account of some important original work on the effect of trace elements.

It is a relief to find a book that deliberately does not discuss the various fluoridation trials in the United States. So much has been written about them and their real and alleged shortcomings that there is a risk of losing sight of one of the fundamental issues—the physiological and biochemical effects of fluorides. Too little is generally known about the systemic effects of fluorides, and Dr. Cannell's book should go a long way towards dispelling this ignorance, especially among the opponents of fluoridation.

The chapters on the pharmacology of the fluorides and on the calcification of skeletal and dental tissues are particularly good. Speculation is kept to a minimum, and the facts are presented fairly, and without bias. Not everyone will agree with Dr. Cannell in his excursion into the field of logical causality (p. 69), but the inescapability of fluorides renders his argument an attractive one.

The final chapter, on the public-health aspects, puts forward a well-reasoned case for the fluoridation of water-supplies. Other possible means of administration are discussed in the light of recent research. The bibliography is comprehensive and up to date, though there is no reference to Mackenzie's extensive review.[1]

This is probably one of the best accounts of fluorides and their effects that has been published for some time.

Pathology of Infancy and Childhood

AGNES R. MACGREGOR, M.D., F.R.C.P.E., F.R.C.O.G., reader in pathology, Edinburgh University. Edinburgh and London: E. & S. Livingstone. 1960. Pp. 631. 75s.

A VOLUME concerned entirely with pædiatric pathology has been urgently needed by many pathologists, and the gap has been partly filled by this book in which Dr. Macgregor incorporates the experience of her many years as an authority on this subject. It is a simple book: it makes no pretension to being a work of reference for pædiatric pathologists, but has been designed for the pathologist whose main work and interests are with older patients. Most conditions which he is likely to meet are considered adequately, with proper regard for their relative importance and incidence. Bearing in mind that the great majority of necropsies are on infants dying in the perinatal period, notes on necropsy technique and detailed practical accounts of perinatal conditions are included. Many facts in this part of the book rarely appear in print and are usually appreciated only after considerable experience. The section dealing with developmental anomalies could have been fortified by the inclusion of notes on embryology, supported by diagrams. Since many hospitals have cardiothoracic units, and deaths from cardiovascular anomalies often form a big part of pædiatric necropsy work, the account of these anomalies may be too superficial. Although the photographs of specimens of malformed hearts are generally self-explanatory, a few diagrams would have enhanced clarity. A lack of uniformity between different sections of the book is mainly due to the omission of conditions which are not peculiar to infants or children, or which are well described in standard textbooks of pathology. But a few relatively important diseases are treated rather briefly, and many less common conditions are not mentioned even by reference to the literature. Although the references are well chosen and up to date, the bibliography will be little help to the pathologist faced with an unusual case.

This book will be particularly useful to those embarking upon a career in pathology or pædiatrics. Its value to the established pathologist is limited, but it will be enjoyed by those who appreciate the signs of the author's wide experience.

The Chemical Senses in Health and Disease

H. KALMUS, SC.D., M.D., reader in biology, University of London; S. J. HUBBARD, B.SC., PH.D., lecturer in physiology, University College, London. Springfield, Ill.: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1960. Pp. 95. 30s.

NO disciple of Brillat-Savarin needs to be reminded of the importance of the chemical senses—concerned as they are with taste and smell. But many may be surprised at the complexity of the physiological processes subserving the art of transcendental gastronomy. Who would have suspected, for instance, that over 60 volatile substances contribute to the aroma of coffee? This suggests almost endless permutation of naturally occurring odours and many kinds of odour-receptors. On the other hand, only four basic tastes—sour, salt, sweet, and bitter—are firmly established. The interplay of taste and smell, the importance of these chemical senses in behaviour both in animals and man, some curious and interesting genetical variations in both senses, and lines of future research and their practical importance are all discussed in this book. The psychological aspects—in some ways the most fascinating of any—are also briefly mentioned. The book is short and well worth the attention of physiologist and clinician. It is a pity the price is so high.

The Early History of Surgery

W. J. BISHOP, editor, *Medical History*. London: Robert Hale. 1960. Pp. 192. 18s.

AT a time when road travel is becoming increasingly dangerous, it is good to discover that some at least of its former hazards have been mitigated. Richard Wiseman, writing in 1676, described the misadventure which befell "a gentleman of about thirty years of age, who was coming out of Hertfordshire through Tottenham and riding upon the causeway near an inn when, one emptying a chamber pot out of the window

deficiency are equally liable to develop advanced megaloblastic anæmia A study of the blood-group distribution of patients with megaloblastic anæmia of pregnancy has shown that cases with a grade-3 type of marrow, in which the classical Ehrlich type of megaloblasts are encountered, probably represent a special group which appears to be genetically determined

---

[1] Mackenzie, E. F. W. *Lancet*, 1952, i, 961.

The blood-group distribution of 175 patients with megaloblastic anæmia of pregnancy was compared with that of 3500 routine antenatal cases in the same district As seen in table I, the only deviation from the norm is an increase in the incidence of blood-group A in patients with megaloblastic anæmia, but this is less than the group A preponderance reported in addisonian anæmia[15]

TABLE I—BLOOD-GROUP DISTRIBUTION IN MEGALOBLASTIC ANÆMIA OF PREGNANCY

Blood group	Routine antenatal (3500 cases)	Megaloblastic anæmia of pregnancy			
		All grades (175 cases)	grade 3 (77 cases)	grade 2 (59 cases)	grade 1 (39 cases)
O	46%	43%	34%	48%	56%
A	42%	50%	60%	46%	36%
B	9%	5%	5%	3%	5%
AB	3%	2%	1%	3%	3%

When, however, cases of megaloblastic anæmia of pregnancy were classified according to their hæmatological grade (from 1 to 3), and the blood-group distribution calculated separately for each grade, it became obvious that there was only one category with a definite group-A preponderance—namely, grade 3—composed of those cases in which the marrow most closely resembles that of addisonian anæmia Table I shows that the incidence of blood-group A in 77 cases in category 3 is 60%, compared with a proportion of 42% in the controls As seen in table II, this difference is statistically significant ($P < 0 01$) On the other hand, the group-A incidence in those patients who were classified in grades 1 and 2 is 42%, which closely approaches the normal distribution

TABLE II—INCIDENCE OF GROUP-A IN MEGALOBLASTIC ANÆMIA OF PREGNANCY

Megaloblastic anæmia of pregnancy	Number of cases	Group A incidence	χ^2	P
All grades	175	50%	4 18	<0 05
Grade 3	77	60%	*9 16*	*<0 01*
Grade 2	59	46%	0 30	>0 5
Grade 1	39	36%	0 43	>0 5
Grades 1 and 2	98	42%	0 04	>0 5
Controls	3500	42%		

Analysis of clinical and hæmatological findings in women with the various grades of megaloblastic anæmia shows that grade-3 cases tend to present with more severe anæmia, higher serum-iron levels, and usually show a greater reticulocyte response to folic-acid therapy In other respects, patients in the various categories do not appear to differ Their age-distribution is similar and the incidence of achlorhydria is approximately the same A history of an inadequate diet in pregnancy appears with equal frequency in all categories, and the previous administration of iron does not seem to affect the marrow-picture Gastrointestinal symptoms, especially anorexia and ulceration of the mouth, occur equally often with lesser degrees of megaloblastosis

It would obviously be premature to draw definite conclusions from the blood-group distribution in a single series of cases from one district These findings suggest, however, that while folic-acid deficiency, with or without megaloblastic changes in the marrow, is a frequent occurrence in late pregnancy, patients with advanced megaloblastic anæmia constitute a special group in which there is an inherited predisposition to the disease The report by Giles and Burton[14] of 13 out of 41 cases of megaloblastic anæmia of pregnancy, with evidence of diminished fat absorption, has already pointed to a constitutional factor in the ætiology of the disease It is perhaps significant that a grade-3 type of marrow was found in 10 of these 13 cases

My thanks are due to Mr A H Iliffe, of the University College of North Staffordshire, for the statistical analysis, to Dr R B McConnell for his helpful advice, to Dr A J McCall for his help and encouragement, and to the research fund of the Birmingham Regional Hospital Board for its assistance

New Inventions

A HEART-LUNG MACHINE FOR INFANTS AND YOUNG CHILDREN

MOST heart-lung machines are designed for patients of 3 to 5 years and over Moreover, particular attention has been directed towards apparatus capable of maintaining the circulation in full-sized adults A number of congenital defects are responsible for death within the first year of life[1], but existing machines, with their relatively large priming volume, are not readily adaptable to the low flows and blood-volumes in this age-group

The following heart-lung circuit has been designed to provide flows up to 1 2 litres per min, with a priming volume of 500–750 ml

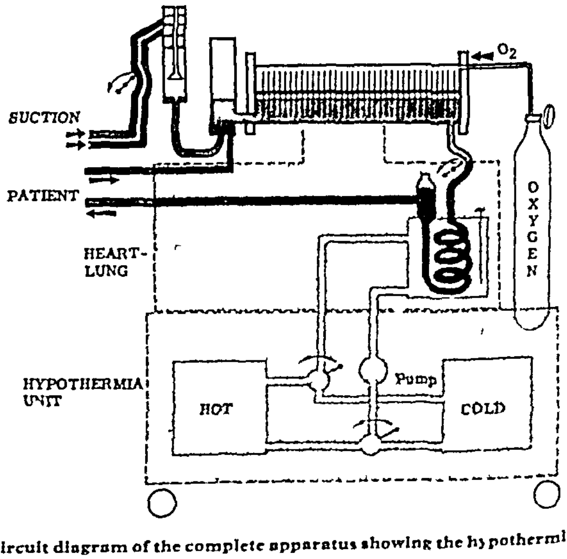
Apparatus

Basically this is a scaled-down version of the model in current clinical use[2] The oxygenator is of the rotating disc variety, and a heat-exchanger is included in the circuit The apparatus is entirely self-contained, being provided with its own source of heating and cooling fluids (see figure)

Two complete oxygenators are available (22 and 34 cm long) The smaller provides for flows up to 700 ml per min, and the larger for flows up to 1200 ml per min The discs are of stainless steel, 7 8 cm in diameter and spaced 4 mm apart Spacing of the discs at less than 4 mm causes foaming No silicone or anti-foam is required in the oxygenator The rotation speed of the discs is 120 r p m

---

1 Bonham Carter, R E , Waterston, D J *Brit Heart J* 1957, 19, 589
2 Ross, D N *Brit med J* 1960, II, 571



Circuit diagram of the complete apparatus showing the hypothermia unit below

Cooling and rewarming is by means of a heat-exchanger constructed from stainless steel. A filter and bubble trap are incorporated in the arterial outflow line. Two sucker lines are provided which deliver their blood on to five perforated plates lightly coated with anti-foam. The output of the arterial pump and of the pump controlling the suction lines can be varied by two simple hand controls. The apparatus and tubing in contact with blood is sterilised in ethylene oxide for 24 hours before use.

The hypothermic and heating equipment is contained within a low trolley which acts as a mount for the heart-lung machine. In this way the apparatus, while remaining compact, is entirely self-contained. The cold source is supplied with a mixture of ice and water kept in a lagged 2 gal. tank, and hot water is kept thermostatically controlled at about 40°C in a separate tank.

Application

The apparatus has been used in twenty-five dog experiments. In addition, four children have been operated on, with one death. In use the machine requires very little adjustment, the running being in the hands of one technician.

The apparatus has been constructed for me by Mr. A. F. Turner in the Guy's Hospital Medical School workshop, and it will be available through Cardiac Recorders, Ltd., Weymouth Street, London, W.1.

Reviews of Books

Medical and Dental Aspects of Fluoridation

W. A. CANNELL, M.R.C.S., D.P.H., L.D.S. London: Lewis. 1960. Pp. 125. 15*s*.

MOST of the growing literature of fluoridation and fluorine is scattered in various journals. A great deal of the research has been done in the United States, and the few books that have appeared since Roholm's classic text in 1937 have been published there. A British survey of the present state of knowledge is welcome, and Dr. Cannell gives a concise and readable summary, with an account of some important original work on the effect of trace elements.

It is a relief to find a book that deliberately does not discuss the various fluoridation trials in the United States. So much has been written about them and their real and alleged shortcomings that there is a risk of losing sight of one of the fundamental issues—the physiological and biochemical effects of fluorides. Too little is generally known about the systemic effects of fluorides, and Dr. Cannell's book should go a long way towards dispelling this ignorance, especially among the opponents of fluoridation.

The chapters on the pharmacology of the fluorides and on the calcification of skeletal and dental tissues are particularly good. Speculation is kept to a minimum, and the facts are presented fairly, and without bias. Not everyone will agree with Dr. Cannell in his excursion into the field of logical causality (p. 69), but the inescapability of fluorides renders his argument an attractive one.

The final chapter, on the public-health aspects, puts forward a well-reasoned case for the fluoridation of water-supplies. Other possible means of administration are discussed in the light of recent research. The bibliography is comprehensive and up to date, though there is no reference to Mackenzie's extensive review.[1]

This is probably one of the best accounts of fluorides and their effects that has been published for some time.

Pathology of Infancy and Childhood

AGNES R. MACGREGOR, M.D., F.R.C.P.E., F.R.C.O.G., reader in pathology, Edinburgh University. Edinburgh and London: E. & S. Livingstone. 1960. Pp. 631. 75*s*.

A VOLUME concerned entirely with pædiatric pathology has been urgently needed by many pathologists, and the gap has been partly filled by this book in which Dr. Macgregor incorporates the experience of her many years as an authority on this subject. It is a simple book: it makes no pretension to being a work of reference for pædiatric pathologists, but has been designed for the pathologist whose main work and interests are with older patients. Most conditions which he is likely to meet are considered adequately, with proper regard for their relative importance and incidence. Bearing in mind that the great majority of necropsies are on infants dying in the perinatal period, notes on necropsy technique and detailed practical accounts of perinatal conditions are included. Many facts in this part of the book rarely appear in print and are usually appreciated only after considerable experience. The section dealing with developmental anomalies could have been fortified by the inclusion of notes on embryology, supported by diagrams. Since many hospitals have cardiothoracic units, and deaths from cardiovascular anomalies often form a big part of pædiatric necropsy work, the account of these anomalies may be too superficial. Although the photographs of specimens of malformed hearts are generally self-explanatory, a few diagrams would have enhanced clarity. A lack of uniformity between different sections of the book is mainly due to the omission of conditions which are not peculiar to infants or children, or which are well described in standard textbooks of pathology. But a few relatively important diseases are treated rather briefly, and many less common conditions are not mentioned even by reference to the literature. Although the references are well chosen and up to date, the bibliography will be little help to the pathologist faced with an unusual case.

This book will be particularly useful to those embarking upon a career in pathology or pædiatrics. Its value to the established pathologist is limited, but it will be enjoyed by those who appreciate the signs of the author's wide experience.

The Chemical Senses in Health and Disease

H. KALMUS, SC.D., M.D., reader in biology, University of London; S. J. HUBBARD, B.SC., PH.D., lecturer in physiology, University College, London. Springfield, Ill.: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1960. Pp. 95. 30*s*.

NO disciple of Brillat-Savarin needs to be reminded of the importance of the chemical senses—concerned as they are with taste and smell. But many may be surprised at the complexity of the physiological processes subserving the art of transcendental gastronomy. Who would have suspected, for instance, that over 60 volatile substances contribute to the aroma of coffee? This suggests almost endless permutation of naturally occurring odours and many kinds of odour-receptors. On the other hand, only four basic tastes—sour, salt, sweet, and bitter—are firmly established. The interplay of taste and smell, the importance of these chemical senses in behaviour both in animals and man, some curious and interesting genetical variations in both senses, and lines of future research and their practical importance are all discussed in this book. The psychological aspects—in some ways the most fascinating of any—are also briefly mentioned. The book is short and well worth the attention of physiologist and clinician. It is a pity the price is so high.

The Early History of Surgery

W. J. BISHOP, editor, *Medical History*. London: Robert Hale. 1960. Pp. 192. 18*s*.

AT a time when road travel is becoming increasingly dangerous, it is good to discover that some at least of its former hazards have been mitigated. Richard Wiseman, writing in 1676, described the misadventure which befell "a gentleman of about thirty years of age, who was coming out of Hertfordshire through Tottenham and riding upon the causeway near an inn when, one emptying a chamber pot out of the window

as he was passing by, his horse started and rushed violently between a signpost and a tree which supported part of the sign. The poor gentleman was beaten off his horse and lay stunned upon the ground." This case, and Wiseman's successful management of it, is one of the many which Mr Bishop uses to illustrate the evolution of surgery. His book is happily written in a style easily intelligible to the layman, yet technical enough to appeal to doctors as well, and, as might be expected from the author's status as an antiquarian, it is distinguished by a meticulous attention to accuracy. Even in such a matter as the emergency operation on King Edward VII, it is noted that it was never officially stated whether or not an appendicectomy had been performed.

The Healthy Child

His Physical, Psychological, and Social Development. Editors HAROLD C. STUART, M.D., emeritus professor of maternal and child health, Harvard University School of Public Health, DANE G. PRUGH, M.D., associate professor of pædiatrics and psychiatry, University of Rochester School of Medicine and Dentistry. Cambridge, Mass.: Harvard University Press. London: Oxford University Press. 1960. Pp. 507. 80s.

THIS book is written for all who work professionally with children, whether in the areas of medicine, education, social work, public health, nutrition, nursing, or psychology, and those who have contributed to it come from a correspondingly wide range of disciplines. The emphasis is on "healthy development" and how it may best be protected or promoted. The book presents in broad terms a picture of the child and his expected progress from conception to maturity. It is concerned with him as an individual who is changing or developing according to natural laws and inborn potentialities. It deals with the major aspects of his physical development and also with his psychosocial development and the factors which favour mental health. Among its many interesting chapters is one on emotional changes in pregnancy. Emphasising throughout the wide range of normal, the book is a valuable contribution to the increasing literature on the important subject of normality.

Life's Long Journey

KENNETH WALKER, F.R.C.S. London: Victor Gollancz. 1960. Pp. 191. 21s.

Mr Kenneth Walker writes, for the general public, to discount excessive claims for the material sciences in general, and in particular the supposition that natural selection sufficiently explains the course of human evolution and that scientific control could or should direct its future course, if any.

In the earlier chapters he seems to postulate "life" as a forward-looking entity planning its own development; but throughout the book "Nature", without inverted commas, appears as experimenter and giver or withholder of gifts, and it is not at all clear whom or what he regards as the "eternal mover", though he makes a firm claim for the life spiritual and the reality of mystical experience.

Like some others, Mr Walker regards the present population explosion as more dangerous to humanity than the atom bomb and fears our despairing recourse to Communist termitism. He is surely unjust to Ecclesiastes ("cast thy bread upon the waters") in ascribing to him and not to Proverbs the advice to look to the ant for exemplar, but that, in the present human predicament, the termitary is terrifying to contemplate is sure enough.

No Crying in this Cradle

The Expectant and Nursing Mother's Bedside Book. ELIZABETH G. MORRISON, S.R.N., S.C.M., M.T.S., JOAN GOLDMAN. London: Ernest Benn. 1960. Pp. 159. 15s.

Elizabeth Morrison has had a vast experience of reading and answering letters from mothers because for thirty years she has run the correspondence columns in *Nursery World*. But one wonders just how much practical experience she has had, and how recently. Some of the advice she gives is outdated—e.g., "it is advisable to go specially easy on meat in the last month or two of pregnancy." There seems little point in advising an expectant mother not to eat mixed grill and telling her that it won't make her or the baby "*feel too good*." The book says that eiderdowns for babies "ought to be forbidden by an Act of Parliament", not because they may smother the baby, but because "*nothing more effective exists to make the baby sweat*." Most of the book is an invective in favour of breast-feeding. But the reasons why babies should be breast-fed whenever possible are poorly argued and unconvincing. It is true that some doctors do not know much about normal babies, but it is doubtful whether many are as woefully ignorant as this book suggests. Doubtless dissatisfied patients write in sorrow and anger to the magazines, and Sister Morrison must receive many such letters. But to describe the doctor and baby clinic as "statistics-ridden prophets" who "yell the roof off with their denunciations" seems to be going rather far.

Nevertheless, the book contains a good deal of sensible, practical advice of the kind that is being given daily by good doctors and nurses up and down the country.

Clinical Bacteriology (2nd ed. London: Edward Arnold. 1960. Pp. 309. 30s.).—The duties of the bacteriologist in a hospital are to isolate pathogenic bacteria, to decide from collateral evidence and probability that these have some connection with the patient's illness, and—a recent development—to give guidance on the treatment of the infection to those responsible for the patient. The identity of the organism is not vastly important (except to the epidemiologist) but custom at least demands that this shall be reported as accurately as possible. It is this academic pride in going beyond the bare diagnosis and treatment which distinguishes the medical bacteriologist from the technician. When Dr Joan Stokes' book first appeared it was the best benchbook for the medical bacteriologist which had been published and it remains so today. The academic background (for which she still apologises) converts what might have been a mere cookery book into a readable and reliable guide to work at the bench. The changes in this second edition add some new methods and take account of some recent advances in knowledge, but as before it is clear that all the recommendations are made in the light of personal experience.

Demonstrations of Physical Signs in Clinical Surgery (13th ed. Bristol: John Wright. 1960. Pp. 928. 75s.).—In 1927 medical illustration was just emerging from the era of line drawings. Some textbooks contained a few photographs, but they were often reproduced in poorly contrasting shades of grey, and the technique of colour printing was in its infancy. When, therefore, in that year, the first edition of this book appeared, with its clear and vivid illustrations, students were quick to appreciate the efforts that Mr Hamilton Bailey and his publishers had made on their behalf. It comes as no surprise to learn that, of the English editions alone, 177,000 copies have now been sold. The latest edition contains more than four times as many pages and illustrations as the first, and if this growth-rate is maintained the twenty-fifth edition may well include *an illustration of the typical lesion* the volume produces by resting on the reader's knees. Many pictures have been furnished by distinguished clinicians, some of whom would no doubt acknowledge that they were helped to their first academic successes by the very work to which they have now contributed.

Principles of Orthopædic Surgery (London: J. & A. Churchill. 1960. Pp. 799. 150s.).—Dr Paul C. Colonna earlier published a book based on his lectures and teaching-rounds at the University of Pennsylvania. This volume is an expanded form (a notable difference is the increased space devoted to traumatic lesions) but has in common with the earlier one a style of writing and printing that makes for easy reading even over long periods. A few of the radiographs are not adequately reproduced, but the work is one of the very few which can be freely quoted on either side of the Atlantic without modification and with equal authority.

THE LANCET

LONDON 12 NOVEMBER 1960

Malaria Research

WHEN LAVERAN discovered the malaria parasite in 1880 he opened the flood gates to a torrent of research which, despite ebbs and flows, today runs as strongly as ever It seemed at various times that the problems of malaria had been finally solved at the end of the century when the mechanism of transmission through mosquitoes was worked out, the way seemed open (or so at least Ross thought) for the control and abolition of the disease, in the years between the wars, and later, a range of drugs was synthesised which seemed to offer the perfect therapy, then the researches on the exo-erythrocytic cycle from 1936 onwards had apparently filled the last gap in our knowledge of the life-cycle of the parasite, while the discovery of dicophane (D D T) and other residual insecticides was thought to have provided the final answer to the problem of mosquito eradication. And today, although we may feel that the end is in sight, this impression may be as false as any similar one expressed earlier in the century

The study of malaria involves so many disciplines that a special composite science—malariology—inevitably developed, with its own institutes, journals, techniques, jargon, and specially its cadre of international workers who have devoted their lives to this fascinating borderline of research The malariologist must be prepared to dabble in entomology and protozoology, in clinical medicine, in chemotherapy and biochemistry, in statistics and genetics, even in such uncongenial subjects as engineering, administration, and sociology An issue of the *Bulletin of the World Health Organisation*[1] illustrates something of this range. It includes a paper by SIR GORDON COVELL (who has been awarded the Walter Reed medal for services to tropical medicine) on the potential danger of apyrexial carriers of malaria in constituting an unobvious reservoir of infection during eradication campaigns, an account by A. S ALVING (Chicago) of a new method of administering primaquine (the drug which destroys the exo-erythrocytic stages of the malaria parasite and prevents relapses) by reducing the toxicity of this invaluable drug, a complete analysis by L T BRUCE-CHWATT and C GOCKEL, of W H.O, of the results of precipitin tests (carried out by B WEITZ, of the Lister Institute) of the stomach contents of anopheline mosquitoes, which showed that 48 out of 51 species fed to a greater or lesser extent on human blood, and other papers dealing with the action of dicophane and other residual insecticides R C MUIRHEAD-THOMSON, and G SACCA and Y GUY show how mosquitoes alter their habits after long exposure to dicophane—the so-called "behaviouristic resistance" The Colonial Pesticides Research Unit at Arusha suggests that the addition of a resin (ceredor) to gamma benzene hexachloride has provided the ideal insecticide for malaria control

Current research in malariology is as eclectic as ever Fundamental studies on the life-cycle of the parasite have been facilitated by using chimpanzees instead of volunteers, and BRAY[2] in Liberia, after finding that the liver of this ape is as susceptible as that of man to *Plasmodium vivax, ovale*, and *falciparum*, successfully demonstrated for the first time the tissue stages of the quartan parasite (*P malariæ*) by this technique There has been much controversy over the nature of nuclear division in malaria parasites, but BANO[3] has clearly demonstrated that the first division of the nucleus of the oocyst is meiotic, and that subsequent ones are mitotic, with a characteristic number of chromosomes in each of the seven species of plasmodia she studied The protective action of sickle-cell hæmoglobin against *P falciparum* was demonstrated by ALLISON[4] and other workers in 1954 and later More recently GILLES et al[5] have suggested that the possession of another hereditary trait—glucose-6-phosphate-dehydrogenase deficiency in red blood-cells—also has an inhibitory effect on the parasite.

Research on resistance has made much progress in the past few years In Algiers, SERGENT and PONCET[6] studied the development of resistance against chloroquine by *P berghei* in rats and mice, and introduced the term "mithridatism" for this feature The work of BISHOP[7] at the Molteno Institute went deeper and indicates that the resistance may have a mutational origin and be concerned with the metabolism of *p*-aminobenzoic acid and folic acid The resistance of several species of mosquitoes to insecticides presents a baffling problem in the eradication programme, and the genetic nature of this phenomenon has been shown at the Ross Institute, where DAVIDSON and JACKSON[8] demonstrated that resistance was of two independent types—to dicophane and dieldrin respectively, arising from single genetic factors, recessive in the former and semidominant in the latter, and applying to species of anopheline mosquitoes from as far apart as Africa, Indonesia, Iraq, and Central America This work has been confirmed to some extent by the cytological studies of FRIZZI and others[9] in Pavia, they have described in great detail the chromosome pattern of several species of mosquitoes, including susceptible and resistant forms These profound laboratory investigations stemmed directly from observations made in the field in Sokotu, Northern Nigeria, where RAMAKRISHNAN and ELLIOTT[10] noticed the sudden resistance to dieldrin of *Anopheles gambiæ* This is a good example of "incidental research", which has been a feature of malariology throughout its history

Animal malaria, which has excited interest from the earliest days, has attracted fresh attention through the discovery[11] in the U S A that a strain of monkey malaria, isolated in London, readily infects man The parasite was named after G BASTIANELLI, the last of the great band of Italian malariologists, who died last year at the age of 96 This organism was being studied in three laboratories in the U S A, and, in all three, accidental infections occurred through the bites of infected mosquitoes The disease proved to be mild, and clinically and parasitologically resembled benign tertian malaria Subsequently G R COATNEY, D E EYLES, M E GETZ, and H K BEYE transmitted the infection back to monkeys and to volunteers, both by mosquitoes and by inoculation of blood containing parasites It was at once realised that here at last was direct evidence that monkeys might act as a reservoir of malaria in Nature, and that this infection might constitute a zoonosis Previously it had been well established[12] that another monkey parasite—*P knowlesi*—could easily affect man in its blood form, but mosquito transmission of this parasite to man has not yet been achieved, other simian parasites, such as *P malariæ* of chimpanzees and *P hylobati* of gibbons, are also suspected but not proved to be zoonoses *P cynomolgi bastianellii* (as this latest parasite is called) originated from a crab-eating monkey (*Macaca irus*) captured in Pahang, and the next stage of the research will be to discover first how many (if any) of the local inhabitants of this forested region are infected with the parasite, and secondly how widely it is distributed in the East Indies, Thailand, and the Far East With such a monkey reservoir of malaria, eradication may be an even more difficult undertaking than it seems at present, but, until the situation has been investigated fully, the extent of the danger cannot be assessed It may even be found that the parasite does not exist in Nature, but was the result of one of the flagrantly unnatural processes to which the parent strain had been subjected it was originally contaminated in both sexual and asexual forms with *P knowlesi*[13], it was flown across the Atlantic in iced blood, and it was maintained in a variety of exotic mosquitoes very different from its original insect vector

If malaria is to be eradicated from the world, these and other problems will have to be solved Even then the subject of malariology will not be extinguished, because much remains unknown about the malaria of lizards and birds, rats and lemurs, and bats and antelopes, and, though their parasites do not appear to affect man, the zoologist will be impelled to investigate them further, with their attendant insect hosts

The Mongol Chromosome and Some Others

THE spate of new observations on human chromosome anomalies continues, and it seems worth following our recent attempt to survey the X chromosome disorders[1] with a similar account of one of the autosomes

Anomalies of the "mongol" chromosome (no 21 on the Denver system[2]) have been most studied indeed, apart from the sex chromosomes, this is the only one that can yet be associated in any but the most tentative way with a definite clinical syndrome Classical mongolism has now been shown beyond dispute to be caused by an extra chromosome, no 21[3-5] "Caused by", we would repeat though we do not know how the effect is produced, the relation is too strong to shelter behind the circumlocutory hedging implicit in the words "associated with" The production of "trisomy" of this kind, with three apparently normal chromosomes instead of the normal pair, by the process of non-disjunction during formation of the gamete, the effect of age on the incidence of non-disjunction, and the consequent explanation of the influence of maternal age on the incidence of mongolism are now familiar themes Interest is concentrating on certain cases in which the effect of trisomy-21 is produced by something other than the usual mechanism Such cases have been sought where youth of the mother, or (more certainly) evidence of familial transmission, has suggested that the ordinary non-disjunction mechanism has not been at work The first of these was reported by POLANI et al[6] earlier this year A mongol girl, one of a number examined because their mothers were much younger than usual at the time of their birth, was found to have the normal total number of 46 chromosomes One chromosome of the very characteristic medium-sized acrocentric group (nos 13–15, the "wishbones") was missing, and instead there was an atypical larger chromosome Ingeniously and most plausibly, POLANI et al accounted for this by assuming that the patient had a third no 21 present (thus accounting for her mongolism) but that this had fused with the missing no 14 (or thereabouts) to give the abnormal larger chromosome ("Fusion" oversimplifies the process, which is probably one of translocation, with exchange of material between two chromosomes if in this process a large fragment of one chromosome is exchanged for a small fragment of another, the result will be a large chromosome carrying most of the material of both and a small one carrying much less When these are separated in the process of gamete formation, imbalance will clearly result)

More recently PENROSE et al[7] have reported further "translocation" mongols One was much like the first, except that the extra no 21 was apparently joined to no 22 instead of no 14 In addition, they reported a most remarkable family Two mongol sibs each had 46 chromosomes, with the same 21/15 translocation-fusion to account for it In addition, three normal female relatives were found to have 45 chromosomes only In them an essentially normal chromosome complement had apparently been affected by the "fusion" of one chromosome each from the pairs 15 and 21 In this family the translocation had obviously occurred at least in the great-grandparents The mere joining together of two chromosomes had no recognisable effect, but the tendency to imbalance during gamete formation inseparable from this fusion gave rise to some offspring with too much chromosomal material, who were the mongols The importance of this form of transmission has been established by the description of a very similar but even larger family group by CARTER et al [8] The mechanism is fairly easy to follow from the diagram (fig 4) of POLANI et al [6]

Another remarkable family was reported by FRACCARO et al [9] Here the mongol patient had 46 chromosomes, and an abnormality of the smaller chromosomes which was thought at first to represent the ordinary mongol trisomy of no 21, with translocatory pseudo-fusion of two of the three to produce an abnormal single larger chromosome His father, who appeared perfectly normal and is a minister of religion (and who may thus be the first exception to the rule that chromosomal anomalies and university degrees are incompatible) was found to have 47 chromosomes and to be trisomic for no 19 The findings in this family admit of no simple explanation with our present knowledge, unless indeed (as seems unlikely) the diagnosis of the child as a mongol is at fault. But clearly we must expect some strange findings from the systematic examination of familial mongols There are rumours of yet other variants on the way

Anomalies of other chromosomes form a much more confusing picture. Trisomies of no 17 [10] and of one of the 13–15 group [11] seem well established Trisomy of no 22 is also not unlikely,[12] though identification of the chromosome present is not very certain (might it even have been an extra Y?) and its relation to the Sturge-Weber syndrome present cannot yet be accepted confidently Trisomy of no 11 [13] and of no 6 [14] have both been claimed, but both cases had the double sex chromatin characteristic of the XXX syndrome,[15–17] and, as we [1] and others [18] have already suggested for the first of these, these may well both be examples of the XXX syndrome with perhaps minor irregularities of one of the X chromosomes concerned Multiple trisomies have also been reported,[19 20] the most striking being FRACCARO et al's case [21] with 49 chromosomes altogether (nos 8 and 11 trisomic, plus XXY), and indeed, except for the viability of the patients, there is nothing incredible about this, for the conditions which cause non-disjunction of one chromosome pair could quite reasonably be supposed equally to affect others Perhaps the most nearly incredible of all the findings is the demonstration by BÖÖK and SANTESSON [22] of trisomy of every chromosome pair, giving a triploid individual with 69 chromosomes

It is too early to hope to decipher the pattern which must lie behind the varied clinical manifestations of these anomalies The sex-chromosome disorders present at least some trace of logic, and mongolism, though we have no glimmer of hint as to the mechanism by which the chromosome defect produces its highly specific effects, presents at least a consistent pattern Of the others hardly any two cases are sufficiently alike for conclusions to be possible It seems not unlikely that there will be found to be some non-specific tendency to congenital anomalies related more to the amount than to the nature of the chromosomal anomaly (mental defect being the most constant element), and a first task will be the identification, behind this screen, of more specific patterns related to disorders of individual chromosomes

The demonstration in viable children of triploidy [22] or trisomy of three large chromosomes [21] at one end of the scale, and in normal individuals of trisomy [9] or translocations [7 8] at the other, shows that the human organism is not as sensitive to such changes as was once supposed Every one of the twelve chromosome pairs of that old friend of the materia medica, *Datura stramonium*,[23] can exist in a trisomic form, and every one has its characteristic phenotype, or, as one calls it in medicine, its characteristic clinical syndrome Perhaps we will soon recognise equally characteristic syndromes for each of our own twenty-two autosome pairs

Tumours of the Bladder

IN the past decade the causes, treatment, and prevention of bladder tumours have aroused much interest. Fascinating questions surround the incidence of this disease Why is it increasing in younger males? Why is it apparently commoner in towns than in the country? Why is it rare in Japan and India? Now that β-naphthylamine is no longer employed in the dye, chemical, or rubber industry, which industries still use carcinogens such as benzidine?

A possible cause of bladder tumours is the excretion in the urine of an abnormal metabolite of tryptophane Some biochemists believe that this metabolite is hydroxykynurenin, others that it is hydroxyanthranilic acid or an allied compound These chemicals can be suppressed in at least three ways by administering pyridoxine, which alters tryptophane metabolism, or by administering saccharolactone, which inhibits enzyme activity in the urine, or by altering the urinary pH. Whether it will be possible by chemical means to prevent so-called "recurring" tumours, which may, in fact, be new tumours due to the persistence of a carcinogenic stimulus, depends on whether the mucosal changes are reversible or whether, once the mucosa has been stimulated by a chemical carcinogen, neoplasia is inevitable even if the stimulus is removed. Double-blind trials now in hand may provide the answer.

In the treatment of the established case one adverse factor that can be attacked is delay. Patients often recognise hæmaturia as a symptom of possibly grave significance. But this view is not always shared by the patient's doctor, who may treat painless hæmaturia, without associated frequency or pain, as a case of cystitis, and when the bleeding stops the patient and his relatives are lulled into a false sense of security. In hospital, too, the possible gravity of the cause of hæmaturia is often not appreciated: recently a patient with this symptom was given an appointment to be seen in the outpatient department three months later. We accept pain in the right iliac fossa as a matter of urgency. Why cannot hæmaturia be given similar priority? In cases of carcinoma of the bladder, when the delay between the onset of hæmaturia and treatment is less than a month the 3-year-survival rate is 70.5%, but when the delay is 6 months the 3-year-survival rate drops to 36.8%.[1] Quick and accurate diagnosis is possible, and this is likelier to improve the results than any changes in the techniques of radical surgery or radiotherapy.

In the past ten years surgery and radiotherapy have each held sway in turn. Nowadays the limitations of surgery and the dangers of excessive radiotherapy are appreciated, the surgeon and radiotherapist work as a team, seeing, treating, and following up each case together. This makes for better results—for example, in cases treated surgically in which metastases develop and require irradiation, and in cases treated by radiotherapy in which surgery is needed for resultant complications.

Many factors, including the age and general condition of the patient, must be taken into account in treating bladder tumours. When the disease is localised and confined to the mucosa the choice lies between intensive diathermy (either cystoscopic or open) or some form of radiation. The complications of intracavitary radiation—contracted bladder, mucosal atrophy, and hæmorrhage—have led to its abandonment in such cases until better techniques can be evolved. Diathermy—either electrocoagulation or electroresection—is therefore the method of choice. The skilled surgeon can deal with even large tumours by this method, but this technique cannot be safely left to a junior. For limited tumours infiltrating no farther than the muscle coat interstitial irradiation may be applied. Formerly such tumours would have been treated by radon seeds, but nowadays artificially produced radioactive isotopes (gold or tantalum) are used. This represents a technical improvement, for radioactive gold grains are smaller, safer, more accurately implanted, and obtainable in various strengths, while tantalum is relatively cheap, has a much longer half-life than gold, and can be kept at hand so that after cystoscopy the bladder can be opened, the tumour excised, and wire implanted at a single operation.[2]

The supervoltage radiotherapy beam, directed either from generators, such as a linear accelerator or a Van de Graaf machine, or from artificially produced isotope bombs (telecobalt or telecæsium units), also has a place in treatment. This therapy can render a bladder tumour-free, but sometimes it completely fails to affect the tumour. Furthermore external radiotherapy in high dosage can produce radiation damage to the pelvic contents, including loops of small intestine. These risks, though small, must be weighed against the possibility of cure and the chance of conserving a normally functioning bladder. Using a linear accelerator at 8 MeV MORRISON[3] found that with a tumour dose totalling 4500–5500 rads in 4 weeks, 31% of patients had no tumour visible on follow-up cystoscopy. There was a better response with the earlier tumours (mucosal tumours disappeared completely in 43%, and a further 19% became appreciably smaller) but the more advanced tumours also regressed in many cases. These results show that supervoltage therapy is an extremely potent weapon and should be considered before recourse to radical surgery.

Partial cystectomy has tended to fall into disrepute, largely because it has been employed in the wrong type of case. MAGRI[4] has found that with single lesions, irrespective of the histological type (80% were solid anaplastic and infiltrating), where a clear margin of at least an inch was obtained there was a 71% 5-year-survival rate. Where, however, the line of excision cut through the tumour or its submucous extensions there were no survivors after 5 years. Partial cystectomy, though fairly easy, should be undertaken only after careful thought.

Radical surgery following radiotherapy is not difficult provided that irradiation has not been applied over too short a time to too large a volume of tissue or in excessive dosage. Radical cystectomy involves the removal of all the pelvic contents except the rectum, and also the lymph-nodes along the iliac vessels. WALLACE[5] has found that this operation, undertaken after radiotherapy, as the last weapon in the therapeutic armoury, carries a mortality of 21%, but that it can prolong life by 3 or more years in half the cases of mucosal tumours, a third of the cases in which muscle is infiltrated, and a quarter of the cases in which the perivesical fat has been invaded.

The treatment of bladder cancer is still far from satisfactory, but much can be done with our present resources to check the disease It is heartening to know that a subcommittee of the International Union against Cancer has agreed on a provisional method of classifying and reporting cases, similar to that adopted for cancer of the breast [6] If this recommendation is accepted the analysis of results should be greatly simplified

POMP AND CIRCUMSTANCE

THE ceremonial ward round has long been a familiar feature of our teaching hospitals The Chief, surrounded by acolytes and disciples, proceeds in pomp from bed to bed, pausing now and then to correct a point of history, to confirm or deny the physical findings, to discuss the differential diagnosis, or to pontificate on methods of treatment. Ward-clerks and dressers stand around, shifting from foot to aching foot, bored registrars converse in whispers, nurses tiptoe past with bedpans, patients lie glum and silent while the Round drones on

Is this the best way of teaching " bedside " medicine and surgery? The *Oxford Medical School Gazette* [7] thinks not In a pungent editorial, entitled " Is Your W.R Really Necessary? ", the *Gazette* reminds us that such methods are frequently discourteous and may sometimes harm patients There the patient lies, sometimes half-naked, a forgotten object while the discussion rages over his bed He is listening, moreover, with apprehension to the list of alarming investigations proposed for him, to talk of frightful-sounding diseases that he might have, sometimes to obvious differences of opinion about treatment The more intelligent and educated he is, the worse his ordeal, for the more likely is he to glean from unguarded remarks some of the grimmer truths about his illness and to penetrate the thin veil of medical euphemisms It is easy to forget that nowadays, thanks to television and other media of mass information, many patients have a smattering of medical terminology and jargon And even if the Round removes itself a few beds away to discuss prognosis, other patients have ears, and ward gossip spreads The physical suffering imposed on ward-clerks by the peripatetic ward round is a less serious matter, but they might listen better and learn more if allowed to sit down comfortably

The *Oxford Medical School Gazette* suggests that all " bedside " teaching should take place in a room adjacent to the ward, with chairs, blackboard, and X-ray screen, into which patients can be brought when needed, or from which the Round can emerge for a brief visit to the bedside This sensible idea has already been adopted by some teaching hospitals We commend it to all Such an arrangement has the additional advantage of ensuring that the formal " round " is recognised as purely for teaching purposes, as it should be, and is not mixed up with the day-to-day management of patients It is impossible to teach properly on more than a few cases at a time Practical therapy should be dealt with by the Chief later, when he goes round his beds privately with his junior staff The traditional royal progress from bed to bed, with a gracious greeting and a few pearls of wisdom dropped at each one, may awe the impressionable but is not the best way either to teach clinical medicine or to cure patients

NEONATAL RESPIRATORY DISTRESS

RESPIRATORY distress in the premature infant is a common cause of neonatal death Most of the affected infants have no evidence of congenital malformation or birth injury, hence they should survive if the distress could be prevented, and their recovery should be complete if it were more amenable to treatment The challenge to obstetricians (for prevention of prematurity is the best means of preventing these deaths) and to pædiatricians is being met, and there is some encouraging progress to report

In the past, research into respiratory distress has been largely concerned with the pulmonary and circulatory aspects [1] This has proved less enlightening than was hoped, for the ætiology of pulmonary hyaline membrane remains obscure,[2] and the reported disturbances in the mechanics of breathing do not add greatly to our understanding, nor do they suggest any sound alternatives to present methods of treatment based on the administration of oxygen and nursing the infant in a humid atmosphere

Interest has turned towards the biochemical changes associated with respiratory distress, and this may well prove a more productive approach The present position has been well summarised by James [3] Infants with birth asphyxia or respiratory distress become severely acidotic with hyperkalæmia, hypoglycæmia, and possibly hypocalcæmia These changes are the expected consequence of anoxia and retention of carbon dioxide They may well be responsible for death, and treatment with glucose, bicarbonate, and insulin holds out some promise of success [4]

The maintenance of a stable blood hydrogen-ion concentration (pH) depends on the lungs and on the kidneys, and the newborn baby is unique in both pulmonary and renal function [5] Some of the peculiarities of this period are now being elucidated Helen Reardon and her colleagues [6] have reported the results of a technically brilliant investigation into the chemical aspects of the control of respiration in the early newborn period They sampled blood not only from the umbilical vessels at birth but also from the temporal artery at various periods afterwards They analysed the blood samples for plasma pH, CO_2 content, protein, O_2 content and capacity, and hæmatocrit From these measurements the pCO_2, buffer base, and oxygen saturation were calculated The results showed that the normal full-term infant is born with mild acidosis which is of both metabolic and respiratory origin This is presumably due to an excess of fixed acids or deficiency of base which is uncompensated by hyperventilation The rise in pCO_2 (respiratory acidosis) suggests that the birth process not only prevents compensation of the metabolic acidosis but leads to impaired CO_2 elimination Within an hour of birth the respiratory component disappears owing to the efficacy of pulmonary ventilation, but the metabolic acidosis (decrease in bicarbonate or other buffer anions) tends to increase There is thus a state of uncompensated metabolic acidosis During the next few hours ventilation becomes efficient enough to compensate for the metabolic acidosis, and in some infants there is evidence of respiratory alkalosis Correction of, rather than compensation for, the metabolic acidosis takes place in breast-fed infants from the 4th day but is delayed in premature infants Reardon et al argue that plasma-pH is the main stimulus to respiration because, during the phase of compensating metabolic acidosis, there is still increased respiratory drive in the presence of lowered pCO_2 and plasma-pH

McCance and Widdowson[7] have shown that the kidney of the newborn infant secretes an acid urine at birth and in the first 48 hours of life, the acidity is due not to acid phosphates but to a predominance of ammonium salts and organic acids, and Zweymuller[8] has identified some of these as emanating from the citric-acid cycle Probably, therefore, the newborn infant depends greatly on pulmonary function for the maintenance of acid-base balance, when this function fails the metabolic sequelæ may be catastrophic, and perhaps the biggest change is the hyperkalæmia Whether this hyperkalæmia is due predominantly to renal retention of potassium and excretion of sodium or to the excessive liberation of potassium from within cells is uncertain It seems reasonable, however, to attempt to prevent the extrusion of potassium from the cells by adequate oxygenation and administration of glucose

PRISONS IN 1959

LAST year, as the annual report of the Commissioners of Prisons[9] relates, the numbers of prisoners grew yet again (though it fell in the autumn), and the numbers of prison staff increased in rather higher proportion, although many more are still needed New legislation had a rather greater effect on the prison population than usual, with a drop of civil prisoners from 744 to 265 due to the Attachment of Earnings Order and an extra 63 prostitutes under the Street Offences Act Imprisonments without fine continued to rise (by over 2500 to 28,411 for men) as did receptions of men not under sentence (by 1000 to 45,000) This means, as the commissioners say, that a regrettably large proportion of the effort of local prison staff is diverted from training persons convicted of crime For women this defect is even more evident, for only 47% of those remanded before sentence were given imprisonment, and some 85% of these were imprisoned for not more than six months There is a widespread feeling that some alternative must be found to short prison sentences, and the new Criminal Justice Bill published last week (its terms are summarised on p 1082) may lead to their abolition at least for young offenders The suspended sentence was buried in 1952, and the Advisory Council on the Treatment of Offenders in 1957[10] did nothing to disinter it The Council did, however, approve adult attendance centres and call for wide use of remand on bail for full inquiry between conviction and sentence, believing that the knowledge gained in this way would help magistrates to avoid giving imprisonment Lord Kilmuir[11] offered detention centres as an alternative for under-21s—a group of prisoners which increased enormously in 1959 (by over 700 to 2498) Nevertheless, for men, sentences of under three months and over three years are tending to diminish slightly and intermediate ones to increase

Regarding types of offence, convictions for violence against the person again increased, though this may only reflect changes in public attitude and sentencing policy Gordon Hawkins[12] has described grounds for believing that in the past half-century violent crimes have not increased significantly Sexual offences continued their downward trend, but not those against females Thefts of all kinds again increased, but imprisonment for drunkenness decreased (by about 200 to 3129) Heavy traffic and current anxieties about road deaths were doubtless partly responsible for the great increase in imprisonment under the Highway Acts—at 2627 the total last year was nearly 50% greater than in 1958 The views of Lady Wootton[13] and others are evidently making some impact on her fellow magistrates (Even so, the Royal Automobile Club[14] has pointed out that, while all traffic offences increased by 6 6% in the year, traffic volume went up by 10%) Local prisons, unfortunately, still carry the greatest load, holding about 4 prisoners to every 1 accommodated elsewhere Clearly "show" prisons such as Wakefield tell but a small part of the story

Breaches of discipline and escapes continued to cause concern Birching was ordered 11 times (3 in 1958), and this punishment was confirmed in 2 cases by the Home Secretary (0 in 1958) That 1 of these 2 men committed a second assault shortly afterwards must reinforce the belief that the value of corporal punishment is mainly to assuage the feelings of the staff In the contrary direction, however, the approach towards a "therapeutic community" proceeds The Norwich system of freer association between staff and prisoners continued to expand, and group counselling[15] spread to fourteen more prisons and borstals in the year Even at Dartmoor, this system has had a good reception Evening classes are expanding, but progress towards the realistic full-time work and reward system, so essential in training a man for ordinary life, is still disappointingly slow Nevertheless, an Advisory Council on the Employment of Prisoners has been set up, together with a new post of assistant commissioner (industrial) It is one of the anachronisms of the age that thousands of able-bodied men moulder away in gaols while public works, such as waterways and the decaying relics of the 1939–45 war, lie neglected But at least the pre-release hostel and training scheme is spreading as its success becomes more obvious Another means of reintegrating the offender with society is by home leave, over 300 borstal lads were thus paroled, and only 1 in 30 broke it

Detention centres remain one of the brighter hopes of the commissioners for coping with the "bulge" of moderately delinquent youth, and the new Bill seeks to make wider use of these centres But, despite great shortage of places, unsuitable lads—persistent offenders, the physically or emotionally disturbed, and approved-school failures—are too often sent to these centres, where they are not helped by the brief period of highly disciplined and energetic life, and where their presence has an adverse effect on others A better system of classification or of advice to magistrates is needed Whether this stern type of institution is more effective than milder methods has still to be shown by valid comparative techniques Over 50% of boys discharged in 1956 and 1957 had been reconvicted by 1960, and this does not sound too hopeful Aftercare, as the commissioners sadly note, is not yet compulsory, but the new Bill includes provisions for its extension to those coming out of detention centres

Physical health in prisons remains good, and the trend towards using outside facilities continues, but the number found insane on remand jumped to almost double despite a decline in the number remanded for mental observation and report It is hard to explain these trends, perhaps the new outlook inherent in the Mental Health Act of 1959 may have permeated the prison medical services more quickly than it has influenced the judicial authorities

The prison services, avowedly therapeutic organisations these days, are under as much obligation as, say, the manufacturers of drugs to assess and to publish their results, particularly where new techniques such as group counselling are introduced In a recent lecture the Home Secretary [16] endorsed the views on research we put forward last year [15] It is therefore disappointing to find so little about new methods in the report In support of group counselling it includes a few staff impressions and a couple of letters from prisoners, only in an appendix is there some worth-while evidence—from a local prison where, despite a rising population, the Norwich system led to a drop in disciplinary reports of 131 to 369, and the continuing lapses were less serious than before Other than this, the cynic might be led to correlate the trend towards easier relationships in and out of the prison with the increase of indiscipline, escapes, and overcrowding which the report mentions A larger chapter on "Research" is needed in this valuable document The Home Office research unit, which is already doing a great deal, should stop hiding its light under a bushel Bricks and mortar may still be badly needed, but knowledge must be given a new priority

HUMORAL AGENT IN MIGRAINE?

BROADLY speaking, the mechanism by which symptoms are produced in an attack of migraine is agreed, but the exact changes in cranial blood-vessels and nearby structures which cause the characteristic head pains are still in dispute

Chapman et al [17] working on the hypothesis that besides local vascular change some inflammatory or pain-producing substance was produced locally, examined tissue-fluid from regions of the head which were tender during a migraine attack Specimens were collected by slowly injecting 2 ml of sterile physiological saline solution into the local subcutaneous tissue and then gently withdrawing some of it Controls were provided by taking samples from the scalps of migraine patients both during attacks and at other times, from people not subject to headache attacks, and from the subcutaneous tissue of the forearms of each subject In the headache subjects a substance was found which bioassay suggested was a polypeptide This substance, for which Chapman et al suggest the name "neurokinin", was present in small quantities in all specimens from all subjects, but very much larger quantities were found in tissue-fluid from the scalp of patients with headaches at the time the specimens were taken It was also found to be released into the segmental cutaneous tissue-fluid during dorsal root stimulation and in the axon flare reaction In one subject the substance was apparently reduced in amount after administration of ergotamine tartrate, and Chapman et al suggest that interference by ergotamine with an enzyme system liberating "neurokinin" from a plasma-globulin may be the basis of this effect

These results are extremely interesting They may possibly explain some of the longer-lasting features of migraine which apparently outlast the aura and headache But bioassay methods can be unreliable, and these findings will need to be confirmed and the substances if possible defined chemically

TUBERCULOSIS IN AFRICA

IN the first of the four Heath Clark lectures, delivered in London on Nov 2, Dr Charles Wilcocks traced the development of investigations into tuberculosis in Africa This disease, he said is still spreading, and drug treatment by itself is unlikely to provide the whole answer

Wide variations in incidence and mortality among different races, noted as long ago as the beginning of the century, had led Cummins to formulate his "virgin soil" theory According to this, primitive tribes were highly susceptible because, in the absence of the bacillus, they had never in their own surroundings been obliged to protect themselves against it, while those living in more urban communities had elaborated protective substances through contact with the bacillus The high tuberculosis incidence and mortality among African troops in Europe in the 1914–18 war seemed to support this theory, though subsequent workers had suggested that the troops involved had been in France for some time and that they broke down under stress in other words, that the cause lay more in the environment than in racial susceptibility

Between the wars extensive work by individuals and commissions, ably supported by administrators, led to an accurate assessment of the distribution and character of the disease It was found to be widely distributed and it progressed rapidly to death, with extensive cavitation and little fibrosis, and usually with involvement of both lungs The sputum was heavily infected, and this was clearly a factor in spread when the patient and the rest of his family slept together in small, poorly ventilated houses

Some idea of the distribution of the disease could be gained from the large proportion—41%—of the total health expenditure of the Union of South Africa devoted to tuberculosis In the mines pneumoconiosis had added to the problem, although more careful selection of recruits and measures to cut down dust had reduced the number affected

Treatment, previously limited to bed rest and an occasional pneumothorax, had been radically changed by the advent of effective drugs But these might fail to control the disease, especially if the patient was not treated in hospital, because many did not take *p*-aminosalicylic acid with their isoniazid, and others stopped treatment before they should Thus resistance developed on a large scale

B C G vaccination was sometimes the only rapidly applicable preventive measure, and its value was probably small But these were short-time measures For widespread improvement, the attitudes of members of very different cultures had to be modified and research undertaken into the means of persuading whole communities to change habits which favoured the development of tuberculosis The most pressing need was improvement in environmental conditions The emphasis had now shifted to stress as the main causal factor in tuberculosis Nutrition, housing, working conditions, and hygiene and sanitation all required attention The £10 million per annum spent by the South African Government in the past five years on housing for non-Europeans was a step in the right direction It was unfortunate that the World Health Organisation, in its last report on the subject, had barely touched on the environmental factor, presumably because it was considered self-evident But anything which was not mentioned tended to be forgotten

It was the doctor's duty to stimulate the administrators to improve conditions, just as had been done in England a century ago

A SEX-LINKED FAMILIAL PURPURA

THE classical sex-linked hereditary bleeding diseases are hæmophilia and its close relation, Christmas disease In the past six years there have been reports of a purpuric hæmorrhagic disorder with a similar mode of inheritance by a sex-linked recessive gene—i e , the condition affects males but is transmitted by female carriers who are unaffected, and each male has an equal chance of being affected or free The condition, first described in 1954 by Aldrich et al ,[1] presents the odd combination of thrombocytopenic purpura, eczema, and undue liability to infection In the family, of Dutch extraction, observed by Aldrich et al , the male infants were known to be liable to die in the first few years of life with " draining ears, eczematoid dermatitis, and bloody diarrhœa ", in the last three generations 16 out of 40 males had died with this disease before the age of 31 months Krivit and Good [2] investigated the same family in 1959 and found that there were 2 female carriers who were reproducing, and that these had had 8 children since 1954, 2 were healthy girls and 6 were boys, of whom 3 had the disease and 3 were healthy

2 cases in an English family have now been reported by Gordon,[3] of Sheffield He points out that seven families affected by the disease have been described, one of them a Negro family Details of 16 male patients are known, and all have died, 1 of Gordon's patients has died, and 1 is still alive

Gordon's 1st patient was admitted to hospital at the age of 14 months with infantile eczema affecting the head, neck, arms, and legs A bleeding tendency had been noted from the age of 4 months, and this had alarmed the mother because she had had a brother who had died of " hæmophilia " at the age of 1 year Investigation showed severe thrombocytopenia, which persisted except for short periods when the count rose above 100,000 per c mm Bone-marrow was found to contain platelet-forming megakaryocytes With treatment the eczema improved, and the patient was sent home He was in hospital again on account of eczema five months later, and at the age of 4 years he was admitted with profuse purpura, bleeding gums, discharging ears, and impetigo The thrombocytopenia being still present, it was decided to carry out splenectomy, and this was followed by a rise of platelets to normal and disappearance of the purpura But in the next twelve months the patient had to be admitted three times—once because he had meningitis due to pneumococcal and staphylococcal infections, once for dental extraction which caused no trouble, and finally in a fatal coma Necropsy showed bilateral adrenal hæmorrhages, there was no evidence of septicæmia, the platelet-count was not recorded

Gordon's 2nd case was the brother of his 1st patient, born eight years later, in between, a healthy girl and a healthy boy had been born This 4th child of the family showed eczema at the age of 3 months, and a month later he was investigated in hospital, he had thrombocytopenia, and furunculosis, pyuria, and bronchitis developed while he was in hospital His white-blood-cell count was normal, and he did not have deficient γ-globulin Treatment with prednisolone and then with corticotrophin produced only a temporary rise in the platelet-count In view of the experience with the elder boy splenectomy was not performed, and the patient has remained reasonably well for three years, still having occasional purpura and occasional attacks of respiratory-tract infection

This syndrome will be easily recognised, though we have no doubt that children with eczema and thrombocytopenic purpura will be seen who do not have the syndrome, the added features of recurrent infection and, above all, a positive family history must also be found The cases so far reported have not been very fully investigated Krivet and Good sought platelet agglutinins but did not find them, marrow punctures have shown the same picture as that of " idiopathic " thrombocytopenic purpura, γ-globulins appear normal But nothing is known about the other blood-clotting factors No attempt seems to have been made to find out whether the condition is linked in any way with systemic lupus erythematosus and similar diseases, in which thrombocytopenic purpura is sometimes an early sign We hope that pædiatricians will look out for cases of Aldrich's syndrome and see whether more can be learnt about its ætiology and possible lines of treatment

CHEMICAL MENINGITIS
FOLLOWING SPINAL ANÆSTHESIA

FORMERLY, when measures were not taken to avoid contamination of the subarachnoid space with phenolic disinfectants, chemical meningitis was a recognised sequel of spinal anæsthesia [1] Sterilisation by autoclaving of special packs containing all the equipment, including the ampoules of local anæsthetic, required for this form of anæsthesia is now commonly practised to prevent this complication But autoclaving by itself is inadequate if the syringes and needles have not been previously freed from all traces of disinfectant by cleansing and washing

The dangers of inadequate washing of equipment are well brought out in an account of five patients in whom acute meningitis developed very shortly after spinal anæsthesia for obstetric delivery [2] The cerebrospinal fluid in each case was purulent, with a polymorph leucocytosis These findings, together with pyrexia, suggested bacterial infection of the subarachnoid space, but no organisms could be isolated from the cerebrospinal fluid or from blood samples A review of the procedures used for cleansing spinal anæsthetic equipment in the obstetric department concerned revealed that, whereas the ampoules of local anæsthetic were taken directly from their carton before autoclaving, the syringes used were soaked in a solution of a phenolic disinfectant, washed and rinsed, and finally put in trays ready for autoclaving Clearly this washing was ineffective Fortunately, all five patients recovered without permanent neurological sequelæ Their illnesses illustrate once again the dangers associated with this mode of anæsthesia when insufficient precautions are taken to avoid contamination of the subarachnoid space

Points of View

FUTURE ROLE OF THE FAMILY DOCTOR*

E MAURICE BACKETT
M B , B Sc Lond , M R C.P , F S S , D P H
PROFESSOR OF SOCIAL MEDICINE IN THE UNIVERSITY OF ABERDEEN

WITH the changing patterns of disease in Western societies, particularly the emergence of the chronic diseases (heart-disease, cancer, peptic ulcer, bronchitis), of accidents (especially motor-vehicle accidents), and of the multiple effects of radiation as the characteristic and newly important threats to the public health, there has come the possibility of a rather different sort of medical care This new approach is preventive in attitude (though the borderline between prevention and very early treatment is rapidly becoming meaningless) It is preventive in the sense of using our growing epidemiological knowledge accurately to define vulnerable groups, families, and individuals in our population and of manipulating their personal and social environment to prevent disease But the differences between the present and future preventive medicine are more important than they seem at first sight These days (and at long last) most of us accept the necessity for clean milk and the quality control of food, for example, without demur These controls are, for the most part, satisfyingly impersonal But just let us try advocating changes in the individual and family dietary customs of the healthy rather than the sick in our practices, or their leisure pursuits, or try to change one of many minor addictions to which we are all prone, and we are in for trouble That trouble is made subtly worse by a sneaking feeling that we may have no right to meddle in these personal matters anyway, and that our techniques, if we do, are naïve Yet, if the future general practitioner is to attempt the control of chronic disease in his practice, he has little choice—he *must* meddle, and his meddling must be increasingly personal, for it seems very likely that before long our so-called " new " diseases will offer as much of a threat to life and happiness as did some of the epidemics of the 19th century And, since many of these diseases have their origins in our changing ways of living, a tolerable amount of interference may help to prevent them

By " new " diseases I do not mean only novelties but *newly important* diseases which, because of their increasing contribution to our morbidity and mortality, must be counted as new threats For example, with the decline (but not the defeat) of the infections we can see more clearly the enormity of our chronic-bronchitis problem (25 million man-days lost per year, and thousands of deaths), of our cancer problem (100,000 deaths per year), of heart-disease, and of chronic but not always fatal diseases like diabetes and multiple sclerosis We see, too, the useless (though fortunately small) waste of fœtal and neonatal life and the few remaining maternal deaths in a new context the context of a society which, perhaps unlike all previous societies, does not expect illness and early death and which thinks of health and happiness as its right

* * *

We can summarise the main features of our changing disease patterns in this way First, the *vulnerable age-groups* are shifting Young people are seldom ill In fact the older children and adolescents have virtually disappeared from the doctor's surgery There is increasing emphasis on the intrauterine child and the neonate, rather than the infant Then there is the new interest, of course, in the elderly, and above all a growing anxiety about the middle-aged The *sex ratios*, too, are changing, and the new diseases are increasingly selective of males

Next, the *type of disease* is changing (and, inevitably, our attitude towards it) For example, infectious disease outbreaks are often spectacular and explosive, cases occur near one another, a hundred or so deaths in a small community has the impact of disaster, while the same number of deaths spread over the whole country—motor-vehicle or coronary deaths, for example—does not carry the same provocative danger signal Some catastrophe is needed to promote social action

Next there is the *duration of illness* Most of our new diseases are chronic slow-moving processes which may take many symptomless years to develop We are told that the cancer of the lung, for example, may have started fifteen or twenty comparatively healthy years before the first symptom of the disease, and that the men now dying of chronic bronchitis may well be reflecting not only their smoking habits and the air pollution of the cities in which they have lived but also the shorter convalescence enforced on working-class families by the tough economic pressures of the hungry '30s It is, perhaps, this very long duration of our chronic diseases and of cancer which is doing most to force us to review our methods of medical care

Finally, we can say that with a few exceptions our new threats to health seem, by their very nature, somewhat less likely to respond to curative medicine than the diseases of the past However, this point is not a strong one, and, to strengthen the case for a review of our preventive measures, I would say that, thanks to the impeccable epidemiology of people like Doll, Case, and Morris, the prevention of many cancers (and some other chronic diseases) is becoming possible long before the disease itself is fully understood Thus, in the face of our new diseases, *prevention* acquires a new urgency, and the wise family doctor is being forced increasingly to switch his attention from sick people to the habits and behaviour of healthy people many years before the clinical onset of illness

* * *

So here, very crudely, is the problem Most people who feel ill seek medical care and have a rather special relationship with their doctors Healthy people, on the other hand, are unlikely to be particularly impressed by talk of a disease which *may* come in twenty years' time Their replies to doctors who seek to change their behaviour, and thus to promote their future health, are polite but negative

The dilemma is most acute for the family doctor, for it is now becoming technically possible for a large part of his job to be the highly scientific supervision of healthy people Indeed, this looks like being the only way to cope with our new diseases Such a statement does not sound particularly surprising, but at the moment well over 90% of the family doctor's work with adults is curative, dealing with established disease If even a quarter of his work were to be concerned mainly with healthy people, rather than the sick, this would be a revolutionary change—at least as revolutionary as was his assumption of the role of vaccinator and immuniser of children Such a change has been made *necessary* by the changes in our disease pattern, and *possible* by a growing knowledge of the reasons for variation in the vulnerability of different age, sex, and social groups This means that the doctor who really knows how his patients live will be able to define with increasing accuracy who is likely to become ill In fact, he alone—because of his contact with the family—can become the man to observe those aspects of behaviour which we suspect are the precursors of much chronic disease

---

* Abridged from a paper read to the sociological section of the British Association on Sept 2, 1960 The full text will appear in *Advancement of Science*

As a help toward the practical application of this change of approach, the doctor now has a growing armoury of screening devices and simple tests by which he can pick the already ill from among the merely vulnerable people in his practice, and so make earlier and ever earlier diagnoses Many of these screening tests are sensitive enough to be used while the patient is still feeling fit—that is before he would normally seek medical care, and long before serious symptoms arise

* * *

These notions may be illustrated briefly by reference to cancer of the uterine cervix Epidemiologically speaking, this cancer is well described A lot is known about what sort of people get it (but, of course, very little about how they get it) Through relatively simple technical advances it is becoming possible to make increasingly early diagnoses of the developing growth We are told that treatment at an early stage is relatively easy and safe, but that the diagnosis must be made before the symptoms and signs develop We are also told that the test is rapidly achieving real accuracy So it is this combination of good epidemiology (which could guide the doctor to where the disease will arise—so that he need not screen all the women in his practice) and this early test which has suddenly given the family doctor the power if not to eradicate the disease then perhaps drastically to reduce it in his practice But, at once we are back with the same problems as before How to persuade apparently healthy women who belong to the vulnerable age, parity, and social group to seek medical care long before they feel ill, how to persuade the doctor to persuade them, and finally, how to fit this approach into a service and a society quite naturally preoccupied with curative medicine

* * *

Tests which can be used for screening apparently healthy populations for all manner of different diseases are rapidly increasing in number and accuracy They are an exciting product of the growing gadgetry of medicine Already it seems probable that more or less accurate and very early diagnoses (that is, long before the patient is conscious of illness) can be made in a variety of chest conditions, a few cardiovascular disorders, some renal diseases, and an assortment of hereditary metabolic upsets, mild diabetes, and at least one cause of blindness

In this way it seems that our new diseases are themselves forcing us into at least the contemplation of a different sort of medical care This medical care may in turn need a rather different sort of doctor to apply it Such a man would have different interests and would need much more time than today's family doctors whose hospital education very properly emphasises curative medicine above all else

There are other difficulties apart from those of time and interest For example, most doctors feel that, at least at first, we should play a passive waiting role the initiative obviously should be with the patient With this in mind most of us would find it very difficult, for example, to write to a lot of healthy adults on our lists *inviting* them to undergo even the simplest of screening tests It would be even more difficult to go to the length of reorganising our practices so that much of our time was spent in this way

There is yet another problem How could the future family doctor screen the vulnerable people on his list, offer his genetic counsel, advise effectively on diet, exercise, and so on, or even check the blood-pressure and weight of the paunchily middle-aged (if one day it is agreed that these too are useful screening tests) without creating not a healthy practice but a practice of neurotics? We have seen a suggestion of this mass fear of illness following the indiscriminate " check-up " campaigns, the cancer films, and the commercial exploitation of anxiety which has occasionally been a feature of " health education " elsewhere Our small experience of studies over here, and the wider experience of calmly and well run studies of community health (such as that at Framingham in the U S A), suggest that these dangers can be avoided But they remain an important threat, and the prevention of some heart-disease, for example, might save the lives of mentally healthy men at the cost of converting them into cardiac neurotics

* * *

Changes in disease patterns must always have given rise to new social problems our current transition from the infections to chronic degenerative disease is obviously no exception The changing role of the general practitioner is among the most intriguing of these problems, and it may be that in future he will have to be prepared to make himself more of a nuisance to his patients But if he does, will they take any notice of him—and why should they anyway?

EAST-WEST SYMPOSIUM ON PATHOGENESIS OF ESSENTIAL HYPERTENSION*

CLIFFORD WILSON
D M Oxon., F.R.C.P
PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON,
DIRECTOR OF THE MEDICAL UNIT, THE LONDON HOSPITAL, E.1

"ALTHOUGH it appears that essential hypertension is a widespread condition and a frequent cause of premature invalidism and death, there is little agreement about its pathogenesis or about the role of various environmental factors in its production. This lack of knowledge prohibits any rational attempt at prevention It seems desirable, therefore, to discuss the conflicting views and to delineate fields in which future research might possibly be concentrated with profit."

These were the broad terms of reference of a symposium which was held in Prague early in the summer under the joint auspices of the European Region of W H O and the Czechoslovak Cardiological Society Some 40 workers, engaged in research on various aspects of hypertension, attended, chiefly from the U S.A , U S S R , and Great Britain, but almost every other country in Europe was represented

The detailed proceedings of the conference will be published shortly, and these will include an account of individual papers and the variety of opinions expressed in discussion Nevertheless it seems worth while to record some personal impressions now which it is hoped may give some idea of the positive achievements of the symposium Research on hypertension has recently received a fresh stimulus from several different directions, and this was reflected in the lively controversy and some new ideas which found expression during the symposium

One stimulus in Prague was undoubtedly the opportunity of hearing from Russian investigators about their concept of essential hypertension as a specific neurosis, against the experimental background of hypertension induced in animals by nervous or emotional strain New interest has also been aroused by epidemiological studies on the role of genetic and environmental factors, one outcome of which is the current controversy on whether essential hypertension is a disease entity or a biological variation differing only quantitatively from the normal Furthermore, the widespread use of hypotensive drugs with a variety of pharmacological effects has not only emphasised the need for a clearer understanding of the fundamental nature of the disorder, but has also produced some new ideas about possible mechanisms in its pathogenesis In the investigation of these problems, statisticians, physiologists, experimental pathologists, and pharmacologists are becoming increasingly active The old controversies about humoral and neurogenic mechanisms have been given a new look by the discovery of intriguing relationships between renin and aldosterone, by more critical assessment of the role of catechol amines, and by the researches of neurophysiologists in several countries on the nervous regulation of the circulation. Added to this is a questioning of the old concepts of the hæmodynamic status in hypertension in which circulatory changes were accepted as incidental to a primary increase in peripheral resistance, so that the search for ætiological factors was focused almost exclusively on this restricted part of the vascular system

The symposium was arranged as a series of discussions on the following topics definition, diagnosis, and natural history, epidemiology, the role of emotional and environmental factors, neurogenic factors in the control of blood-pressure, hæmodynamic studies in essential hypertension, vessel-wall factors, metabolic factors, including the possible role of pressor amines, the adrenal cortex, and the kidney

Although there was considerable divergence of opinion on most of the topics discussed, there was a fair amount of agreement on the nature of the problems which need to be tackled These I have attempted to summarise in the following questions

(1) In the light of modern knowledge, can we arrive at any more satisfactory definition of essential hypertension than the present one of "elevation of the blood-pressure without apparent cause"?

(2) In view of the more exact methods of diagnosis now available, how large a proportion of cases, masquerading under the diagnosis of essential hypertension, are really due to some local disease—e g , of the kidneys or endocrine glands?

(3) Is it possible to find a means of separating normal from high blood-pressure, not only in the numerical sense, but also in establishing whether essential hypertension is qualitatively different from the physiological range of the blood-pressure?

(4) How valid are casual blood-pressure readings, especially when used as an index in epidemiological studies? How far can such blood-pressure readings be standardised?

(5) How large a part does heredity play in the pathogenesis of essential hypertension? Is the genetic factor sufficiently large to indicate a primary metabolic fault in blood-pressure regulation as the main cause?

(6) What is the role of environmental factors such as geographical situation, diet (including electrolyte intake), occupation, and particularly, mental strain or emotional stress?

(7) Does the blood-pressure rise with age uniformly in the population as a whole, or is there an excessive rise in a limited group, who as they get older emerge from the normal population owing to the development of a specific disease, essential hypertension?

(8) How often does "transient" or "intermittent" hypertension lead to established hypertension—i e., is there a definite sequence in the natural history from transient to permanent elevation of the blood-pressure?

(9) Can a prehypertensive state be recognised in which metabolic or vascular responses may make it possible to anticipate the development of essential hypertension?

(10) What part do nervous, renal, and endocrine mechanisms play in determining peripheral vascular resistance? Is there any real evidence that these factors play a different role at different stages of the disease?

(11) Is the regional distribution of increased peripheral resistance the same in all cases? Is it different in the early and late stages, and does it differ from the distribution in other hypertensive disorders such as renal hypertension?

(12) Is it possible that, with advancing age, some alteration in the vessel wall may produce a change in reactivity to physiological stimuli?

For the various topics in the symposium, discussion leaders were appointed, and produced a day-to-day progress report In the final discussion on "topics and future trends for research arising from previous discussions " an attempt was made to coordinate the results of the conference, particularly with a view to international co-operation in various fields In what follows, I have tried to give a brief account of the general conclusions on the various topics seriatim, but it must be recognised that on some issues there is still considerable disagreement on both the validity and the interpretation of the available evidence, or on its relevance to essential hypertension

---

* This article is based on a summary review of the symposium presented to the Czechoslovak Cardiological Society, and a lecture on experimental hypertension to the Czechoslovak Nephrological Society, Prague, June, 1960

Definition and Natural History

On the question of *definition* it was generally agreed that at present there is no satisfactory alternative to the term essential hypertension, indicating " a common form of high blood-pressure without apparent cause " Whilst modern diagnostic techniques are revealing increasing numbers of cases due to specific lesions, such as renal-artery stenosis, pyelonephritis, or endocrine disease, this is almost certainly a minority group—not large enough, for example, to invalidate epidemiological studies based on measurements of blood-pressure as the sole criterion In the individual it is impracticable to define a critical dividing-line between normal blood-pressure and essential hypertension but this is equally true of other forms of hypertension—e g , that due to renal disease Whether essential hypertension is a disease entity, qualitatively different from the physiological range of blood-pressure, may well be decided by a critical analysis of existing epidemiological data, together with further planned investigation of selected populations If indeed we are dealing with a specific disease, some biochemical fault should eventually be discovered There is evidence that patients with essential hypertension do show qualitative differences from the normal—for example, rapid electrolyte diuresis following plasma-volume expansion by a water or solute load, reversal of the normal antidiuretic effect of injected angiotensin, and the recent evidence of increased secretion of aldosterone in malignant hypertension—but it has yet to be shown that these differences in behaviour are specific for essential hypertension and that they are primary rather than secondary manifestations

One of the most urgent needs is a clearer definition of the *natural history* of the disorder Physiologists, experimental pathologists, and epidemiologists are tending to interpret their various data in terms of the " early " or " late " stages of the disease, but there is as yet no clear understanding of these stages or indeed of the relationship of transient to established hypertension It may well be that further clarification of the natural history will emerge from characterisation of the various states (if these exist) by biochemical or physiological tests Thus, response to salt-loading or angiotensin, or differences in secretion, utilisation, or end-organ response of adrenal cortical hormones, may be found to differ in different clinical groups, or again there may be a change in hæmodynamic pattern in terms of cardiac output and distribution of regional resistance Possibly nervous and humoral factors play different roles in the early and later stages We know, for example, that a minority of cases, especially in young subjects, have an increased cardiac output Whether this is due to anxiety at the time of the investigation and whether it can still be demonstrated after hypertension has persisted for many years needs to be determined Whilst some of these questions—e g , a better definition of stages of the disease—may be answered by large population studies, most of them will require long-term and more detailed investigation of small numbers of patients by the clinician and experimentalist working together For, apart from problems of differential diagnosis, it will be essential to recognise the intrusion of secondary factors, such as local atherosclerosis, altered renal function, or emotional reactions, which may modify the physiological pattern and bring into play new homœostatic mechanisms

Epidemiology

The starting-point of epidemiological studies is the validity of blood-pressure estimation as an index Examination of the " casual " blood-pressure should be made to see whether further standardisation of technique is possible and what additional criteria can reasonably be included in population studies The epidemiologist is on uncertain ground until the validity of the high casual pressure as an indication of essential hypertension is assured But if this can be established, some of the really fundamental problems of ætiology may be solved by epidemiological methods The most important of these is *heredity* If the genetic factor in essential hypertension is of major importance there is an urgent need to seek for an inborn error of metabolism in the pathogenesis of the disease Even if there is a specific genetic factor, the environmental situation may well determine whether this defect leads to manifest disease Furthermore a distinction (commonly overlooked) must be made between genetic factors and the " cultural inheritance " which is also transmitted in the family The influence of *age* is the second main problem which epidemiological studies should be able to resolve, for if a substantial rise in blood-pressure can be shown to develop in a discrete section of the population as age advances, in contrast to little or no rise in the remainder, there can be little doubt that essential hypertension exists as a separate entity, furthermore the search for a causal mechanism can then be directed to changes in function with advancing age There is a good deal of evidence, at present difficult to evaluate, of blood-pressure differences between population groups, which may be related to ways of life It is in the epidemiological field that international cooperation is likely to be most fruitful, particularly in the investigation of racial factors, the effects of diet, the stresses of industrialisation, and other circumstances where differences in prevalence, already recognised, present " experiments of opportunity "

The Neurogenic Hypothesis

The view that essential hypertension has a neurogenic basis is undoubtedly enjoying a new wave of popularity Investigators in the Soviet Union have for some years maintained that essential hypertension develops as a specific manifestation of neurosis, and this has led to observations on the prevalence of hypertension in different occupation groups, to extensive physiological researches on the nervous regulation of the circulation, and to studies in dogs and monkeys of experimental hypertension produced by stress stimuli using conditioned reflexes and Pavlovian techniques The widespread use of hypotensive drugs which act centrally or peripherally by inhibiting autonomic vasoconstriction has produced in some quarters an uncritical acceptance of the neurogenic theory, or at any rate of an important nervous component in essential hypertension Supporting evidence has been sought, particularly in the United States, by analysing the emotional and hæmodynamic responses of hypertensive individuals to stressful situations, or by studying cultural background, character structure, and behavioural patterns in relation to the incidence of the disease. Owing to lack of translations of published data it is impossible to give a fair assessment of the Russian view, and it is to be hoped that the clinical, experimental, and epidemiological evidence on which this concept is based will soon be made more readily available. At present most workers agree that in the established phase of essential hypertension—i.e., when the diastolic pressure is persistently raised—there is no convincing evidence that the cause is neurogenic vasoconstriction. That emotional stress can cause acute elevation in blood-pressure is undoubtedly true, but the relevance of this to the chronic disorder we term essential hypertension is quite obscure, and in neither transient nor established hypertension has increased autonomic activity been demonstrated by the finding of increased catechol-amine production, as is observed in patients with high blood-pressure due to phæochromocytoma. There is obviously a need for a more critical and broadly based assessment of hypertension of supposedly nervous ætiology in terms of its clinical characteristics, hereditary origins, and subsequent course. Furthermore when studying emotional responses in both personal behaviour and vascular reactivity, it is essential to establish to what extent these are the cause or the result of the elevated blood-pressure.

Hæmodynamic Changes

From what has been said it will be obvious that the largest single obstacle to understanding the genesis of hypertension is an imperfect knowledge of the factors which control the blood-pressure in health. It would be easier to decide whether hypertension was "abnormal" if we understood better the mechanisms by which normal blood-pressure is maintained. This becomes even more obvious when considering the further problems of hæmodynamic changes, vessel-wall factors, and the possible role of renal and endocrine dysfunction in essential hypertension. In the field of blood-pressure regulation, physiologists seem to have been until recently almost exclusively concerned with the autonomic control of vascular tone. In various discussions a great deal was heard about the baroceptors and other vascular receptor mechanisms, about cardiovascular changes following hypothalamic stimulation, and about the central and peripheral effects of hypotensive drugs on autonomic status and catechol-amine production. It is well established that the response threshold of the baroceptors is raised in chronic hypertension, but this appears to be an adaptation to the high blood-pressure rather than its cause. Recent physiological and pharmacological work has certainly revealed new aspects of neurogenic control of the circulation, but those who are concerned with the problem of hypertension, either clinically or experimentally, are questioning the adequacy of this approach, and are seeking information on other possible regulating mechanisms which may be more relevant in maintaining blood-pressure at a high level. For example, what controls the residual arteriolar tone when all sympathetic influences are removed? Is it some endocrine factor, a renal pressor substance such as angiotensin, or is it a question of the electrolyte environment of the smooth-muscle cells of the arteriole? Whatever the controlling factors, vessel tone varies under the influence of a number of stimuli, and this brings up the vexed question of vascular reactivity. Pressor responses to vasomotor stimuli such as cold, emotion, and vasoconstrictor drugs have so far failed to provide a convincing separation of hypertensive from normotensive subjects or to predict the future development of high blood-pressure in the latter. Yet the level of the blood-pressure alone is insufficient to explain individual differences in the production of both functional and structural vascular reactions—e.g., hypertensive headache, papillœdema, fibrinoid arteriolar necrosis and localised cerebral vasoconstriction in hypertensive encephalopathy.

In general the view has long been accepted that narrowing of the arterioles is the primary hæmodynamic change in essential hypertension. An alternative view is that vasoconstriction may occur as a reaction to increased intra-arterial pressure, which might be caused, for example, by a rise in cardiac output. This possibility has directed attention to primary changes in cardiac dynamics and to possible alterations in venous tone or venous blood-volume, which might affect cardiac output and thereby initiate arterial hypertension. Deviations from normal behaviour, such as the rapid salt diuresis in chronic hypertension, and the link between reduction in plasma-volume and blood-pressure after administration of diuretics such as chlorothiazide, have suggested a disturbance in the relationship between vascular capacity and blood-volume in the hypertensive patient. Various new and interesting techniques are being developed in an attempt to explore these possibilities. Methods have been devised for a more exact physical analysis of the parameters of vascular tone, and it is hoped that these may provide a means of identifying and assessing the effects of neurogenic and humoral factors, and of vascular "reactivity", in hypertension of various sorts. Hæmodynamic studies on cardiac output, and on the regional distribution of peripheral resistance, suggest that in hypertension certain areas of the vascular bed—e.g., the kidneys and skeletal muscle—respond differently in different circumstances. Experimental models are also being devised in animals in an attempt to separate the cardiac component from the role of the peripheral circulation during changes in blood-pressure induced by various means.

Metabolic Factors

The symposium included a number of papers and a very critical discussion on the role of pressor amines, the adrenal cortex, and renal factors in the pathogenesis of essential hypertension. Most workers agreed that at present there is no direct or convincing evidence that either the kidney or the endocrine system plays a part in the early or later stages, although this may not be true in the malignant phase of the disease. Here again we are faced with the problem of distinguishing primary factors from secondary changes which develop in severe hypertension as a result of renal vascular damage. Such damage may produce metabolic disturbances—for example, in sodium and water excretion—and may possibly alter the pattern of hormone production (e.g., hyperaldosteronism in malignant hypertension). Nevertheless recent work on the reciprocal action of renin and aldosterone, and on the relationship of renin production by the juxtaglomerular apparatus to renal perfusion pressure, have produced, if not yet a promise, at any rate a hope, of a clearer understanding of renal participation in blood-pressure regulation.

There is another line of approach, based on both clinical

and experimental observations, which is certainly relevant to the problem of chronic hypertension in general, and possibly by analogy to essential hypertension This is the growing evidence of a change in mechanism when high blood-pressure passes from the acute to the chronic stage Thus when hypertension is caused by some specific lesion—e g , phæochromocytoma, adrenal cortical tumour or unilateral renal disease—the pressure frequently remains elevated when the primary cause is removed As far as present evidence goes, it does not seem possible to distinguish this chronic residual hypertension from essential hypertension on clinical, physiological, or anatomical grounds There is some evidence also of a difference in mechanism between the hypertension of acute and chronic nephritis and early and late experimental renal hypertension These observations underline the importance, first, of looking for a similar change in mechanism in the development of essential hypertension, and, second, of considering the possibility of a common factor in the various forms of chronic high blood-pressure The striking thing is that in all these conditions a new equilibrium appears to have been established at a high level of blood-pressure which is consistent with many years of good health This would appear to involve a " resetting " of the homœostatic mechanisms which normally maintain arterial pressure at a steady level There is evidence of such a resetting in the case of the baroceptors, but, as already mentioned, the evidence does not suggest that this is of causal significance One of the most clear-cut observations in this field is the reversibility of chronic renal hypertension In the laboratory animal, renal hypertension of long duration is reversed within a matter of hours if the renal circulation is restored to normal In man a similar prompt reversal of chronic renal hypertension has been demonstrated when, in identical twins, a normal kidney has been grafted in a twin with chronic nephritis and the diseased kidneys removed Thus it is clearly established that, in the maintenance of chronic renal hypertension, no irreversible extrarenal mechanism—structural or neurogenic—supervenes This does not of course exclude the participation of some extrarenal factor, but it does indicate that in this form of chronic hypertension a metabolic renal disturbance almost certainly plays a primary role in resetting the homœostatic regulation of the blood-pressure at a higher level In other forms of chronic hypertension, including essential hypertension, this line of reasoning is effectively blocked by the fact that, at any rate until the late stages, there is no structural basis for a renal mechanism If therefore the kidney plays a role in the pathogenesis of essential hypertension it must be on the basis of a purely functional disorder, or of structural changes which have not been so far revealed by light microscopy This is a main problem for future investigation One of the most urgent needs is a further clarification of the mechanism of renal hypertension, for, from what has been said, this may open the way to an understanding of other forms of chronic high blood-pressure

Views on the pathogenesis of essential hypertension have recently been expressed, on this and other occasions, in which the high blood-pressure is deemed to depend on a variety of influences—genetic, nervous, emotional, dietary, renal, and endocrine—with the corollary that no specific cause is likely to be found in the great majority of cases These " multiple choice " hypotheses, which embrace all the possible mechanisms of blood-pressure variation, fail to distinguish, and indeed seem to discount the need to distinguish, these mechanisms from their provoking causes The modes of production of blood-pressure elevation are undoubtedly manifold and may differ in the wide variety of individuals who present with arterial hypertension But some single factor or limited combination of specific factors may well determine that one person gets " essential hypertension " whilst another does not

Conclusion

From these far-ranging discussions I have attempted to outline recent trends in various lines of research which seem to offer promise for the future The Prague symposium made a valuable contribution by bringing together workers from East and West, and by providing the fullest opportunities for critical discussion of their diverse views It brought to the fore the problems and possibilities of epidemiological research on the subject, and presented fresh evidence and ideas on hæmodynamic factors Perhaps of greatest importance was the large representation from the basic sciences—chemistry, physics, physiology, and pharmacology—for from these disciplines are most likely to come new techniques and methods of inquiry

The programme arrangements of the symposium placed the emphasis on discussion rather than presentation of papers, and this was something of an experiment on which both W H O and the Czechoslovak Cardiological Society are to be congratulated What cannot be omitted is a sincere appreciation of the work and friendliness of our medical colleagues in Prague, whose hospitality was not only generous but very largely personal and spontaneous

THE FUTURE OF GENERAL PRACTICE

THE future of general practice was considered by Dr OSCAR WILLIAMS in a presidential address to the Association of Welsh Executive Councils at Llandudno on Oct 28

Dr Williams remarked that it had been said that the general practitioner was dead It was certainly true that, except in residential suburbs and south-coast resorts, applications for practice vacancies had fallen almost catastrophically What was to be done ?

The clock could not be put back no practitioner could now, as he did formerly, cope with all emergencies and problems But the pendulum had swung too far the other way, for today the practitioner was forced to refer a high proportion of his patients to a specialist or a succession of specialists before initiating treatment, and sometimes he might lose all control over his patient's treatment

Inevitably the status of the practitioner (he could now hardly be called family doctor) had suffered—and this at a time when in the higher administrative places opinion was moving away from increased institutional treatment, particularly of mental illness, of the very young and very old, and even for midwifery

Those who served on executive councils should welcome this rethinking, and should determine forthwith to play a more creative part in building a complete domiciliary service—an aim which could be achieved only in cooperation with the public-health, hospital, and social services The general practitioner could then become more of a personal doctor, concerned with the social aspects of disease, able and willing to advise the family on its problems, the children, the aged dependants, and the difficulties when the family had to cope with a mentally ill member

Unfortunately there was at present little incentive to this end The Royal Commission on the Remuneration of

Doctors and Dentists had not supplied the answers its report implied that indifferent work paid The essential minimum requirements were as follows

The practitioner should have more time to devote to each patient, and this entailed at once cutting big lists and lowering maxima

He should be properly housed, with all the ancillary help he needed.

He should work closely with his hospital and other colleagues, and he should in fact be invited to participate actively in the work of the hospital and of local-authority clinics, thus averting the frustrations of overlapping

He should be allowed far more practical participation in the work of hospitals Clinical assistantships limited to six months' tenure were not the answer, nor even was the provision wherever possible of general-practitioner beds A family doctor should be able to graduate into the hospital service, as he could formerly

Another difficulty, which had been only half faced, was the general practitioner's security, or lack of it The doctor should have the right, without fear of losing his patient, of advising the patient firmly on the course he should pursue, and not merely prescribe the latest tablet A change of doctors should not be allowed without adequate grounds Finally, there should be some recognition of higher standards of work

PENSION AND BENEFIT INCREASES

The proposed increases in pensions, benefits, and contributions, foreshadowed in the Queen's speech, were announced by Mr John Boyd-Carpenter, Minister of Pensions and National Insurance, on Nov 2 The increases, which will cost an extra £160 million a year, will, subject to parliamentary approval, begin next April

War Pensions

The basic rate of pension for 100% war disablement will be raised by 12*s* 6*d* a week to 97*s* 6*d* Pensions for war widows with children, or over forty years of age, will be increased by 10*s* a week to 76*s*, with further increases for their children.

National Insurance Benefits

The standard rates of retirement and widows' pensions and sickness and unemployment benefits will go up to 57*s* 6*d* a week for single people and to 92*s* 6*d* a week for married couples, increases of 7*s* 6*d* and 12*s* 6*d* respectively The allowance for each dependent child will be increased by 2*s* 6*d* a week, and for a widow's child by 5*s* Maternity benefits, the guardian's allowance, and the child's special allowance are also being raised

Industrial Injuries Benefits

Injury benefit, now 85*s* a week, will be increased to 97*s* 6*d* a week as will the pension for 100% disablement. The industrial widow's pension of 56*s* a week will go up to 64*s*

Contributions

The flat-rate contributions for employees in the graduated scheme will stay at about their present level instead of being reduced from next April The flat-rate contributions for employees contracted out of the graduated scheme, for the self-employed, and for the non-employed will be increased. The contribution from the taxpayer will also be increased.

National Assistance

The scale rates for National Assistance will be raised by 3*s* 6*d* a week for a single householder and by 5*s* for a married couple, to 53*s* 6*d*. and 90*s* respectively There will be suitable increases in the other rates, including those for dependants

Symposium

IMMUNOLOGY IN THE RHEUMATIC DISEASES

The Empire Rheumatism Council held a symposium on Immunology in the Rheumatic Diseases in London on Oct 28, under the joint chairmanship of Dr W S C Copeman and Prof John Squire

Dr L E Glynn (Taplow) said that immune tolerance was an acquired faculty, but one which could also be lost He outlined possible ways in which antigen- or antibody-forming cells might be altered with subsequent breakdown or avoidance of tolerance mechanisms

Dr A. G S Hill (Stoke Mandeville) reviewed the clinical evidence that rheumatoid arthritis was a disordered immune response, and found little to indicate a hypersensitivity response

Reporting a joint study with Dr I M Roitt, Dr W Hijmans (Leiden), and Dr E J Holborow, Dr Deborah Doniach (London) described results of testing sera from patients with thyroiditis, systemic lupus erythematosus (S L E), and rheumatoid arthritis for the presence of antibodies to thyroid antigens, antinuclear factors, anticytoplasmic factors, and rheumatoid factors About 10% of Hashimoto patients gave positive antinuclear or anticytoplasmic tests, and the incidence of low-titre anti-thyroglobulin antibodies was increased in S.L.E patients

Serum complement was diminished in S.L.E., Dr H A. Ellis (Birmingham) found, and might be increased in early active *rheumatoid disease, although it fell later, especially* when rheumatoid-factor titres were high.

Dr R. R. A Coombs (Cambridge) described the factor—immunoconglutinin—which appears in the serum of rabbits immunised with bacteria specifically agglutinated with antibody in the presence of complement, or indeed immunised with bacteria alone This factor, apparently an auto-antibody to complement, can be detected in the serum in many human infections, but is increased also in rheumatoid arthritis

Dr R. G White (London) described the use of immunofluorescent methods to locate γ-globulin intracellularly in the plasma-cell series in the medullary tissue of lymph-nodes, and in their germinal centres He drew attention to the follicular hyperplasia and plasma-cell proliferation found in rheumatoid lymph-nodes

The significance of the rheumatoid serum factors was discussed by Dr J Ball (Manchester), who said that the rheumatoid macroglobulin factor for rabbit globulin could be detected in about 40% of adults, and in significant titre in 2–5% of Northern Europeans Positive tests were found (apart from rheumatoid arthritis) in a significant proportion of cases of S L E, systemic sclerosis, digital arteritis, and Sjogren's syndrome About 35% of positive tests in a random sample were associated with clinically detectable disease.

Dr C L Greenbury (Stoke Mandeville) described quantitative experiments using radio-iodine to label rheumatoid factor or antibody, which indicated that the amount of factor removable by repeated absorption from a given serum varied according to the degree of sensitisation of the absorbing red cells

Dr B Cruickshank (Glasgow) doubted whether γ-globulin was significant in the ætiology of rheumatoid disease Only a minority of the plasma-cells in the inflammatory lesions of rheumatoid tissue had been shown to contain either 7S or 19S γ-globulin He had found histological changes in synovial tissue in ankylosing spondylitis essentially similar to those in rheumatoid arthritis, but associated neither with serum

and experimental observations, which is certainly relevant to the problem of chronic hypertension in general, and possibly by analogy to essential hypertension This is the growing evidence of a change in mechanism when high blood-pressure passes from the acute to the chronic stage Thus when hypertension is caused by some specific lesion—e g , phæochromocytoma, adrenal cortical tumour or unilateral renal disease—the pressure frequently remains elevated when the primary cause is removed As far as present evidence goes, it does not seem possible to distinguish this chronic residual hypertension from essential hypertension on clinical, physiological, or anatomical grounds There is some evidence also of a difference in mechanism between the hypertension of acute and chronic nephritis and early and late experimental renal hypertension These observations underline the importance, first, of looking for a similar change in mechanism in the development of essential hypertension, and, second, of considering the possibility of a common factor in the various forms of chronic high blood-pressure The striking thing is that in all these conditions a new equilibrium appears to have been established at a high level of blood-pressure which is consistent with many years of good health This would appear to involve a " resetting " of the homœostatic mechanisms which normally maintain arterial pressure at a steady level There is evidence of such a resetting in the case of the baroceptors, but, as already mentioned, the evidence does not suggest that this is of causal significance One of the most clear-cut observations in this field is the reversibility of chronic renal hypertension In the laboratory animal, renal hypertension of long duration is reversed within a matter of hours if the renal circulation is restored to normal In man a similar prompt reversal of chronic renal hypertension has been demonstrated when, in identical twins, a normal kidney has been grafted in a twin with chronic nephritis and the diseased kidneys removed Thus it is clearly established that, in the maintenance of chronic renal hypertension, no irreversible extrarenal mechanism—structural or neurogenic—supervenes This does not of course exclude the participation of some extrarenal factor, but it does indicate that in this form of chronic hypertension a metabolic renal disturbance almost certainly plays a primary role in resetting the homœostatic regulation of the blood-pressure at a higher level In other forms of chronic hypertension, including essential hypertension, this line of reasoning is effectively blocked by the fact that, at any rate until the late stages, there is no structural basis for a renal mechanism If therefore the kidney plays a role in the pathogenesis of essential hypertension it must be on the basis of a purely functional disorder, or of structural changes which have not been so far revealed by light microscopy This is a main problem for future investigation One of the most urgent needs is a further clarification of the mechanism of renal hypertension, for, from what has been said, this may open the way to an understanding of other forms of chronic high blood-pressure

Views on the pathogenesis of essential hypertension have recently been expressed, on this and other occasions, in which the high blood-pressure is deemed to depend on a variety of influences—genetic, nervous, emotional, dietary, renal, and endocrine—with the corollary that no cause is likely to be found in the great majority s These " multiple choice " hypotheses, which race all the possible mechanisms of blood-pressure variation, fail to distinguish, and indeed seem to discount the need to distinguish, these mechanisms from their provoking causes The modes of production of blood-pressure elevation are undoubtedly manifold and may differ in the wide variety of individuals who present with arterial hypertension But some single factor or limited combination of specific factors may well determine that one person gets " essential hypertension " whilst another does not

Symposium

IMMUNOLOGY IN THE RHEUMATIC DISEASES

THE Empire Rheumatism Council held a symposium on Immunology in the Rheumatic Diseases in London on Oct 28, under the joint chairmanship of Dr W S C COPEMAN and Prof JOHN SQUIRE

Dr L E GLYNN (Taplow) said that immune tolerance was an acquired faculty, but one which could also be lost He outlined possible ways in which antigen- or antibody-forming cells might be altered with subsequent breakdown or avoidance of tolerance mechanisms

Dr A G S HILL (Stoke Mandeville) reviewed the clinical evidence that rheumatoid arthritis was a disordered immune response, and found little to indicate a hypersensitivity response

Reporting a joint study with Dr I M ROITT, Dr W HIJMANS (Leiden), and Dr E J HOLBOROW, Dr DEBORAH DONIACH (London) described results of testing sera from patients with thyroiditis, systemic lupus erythematosus (S L E), and rheumatoid arthritis for the presence of antibodies to thyroid antigens, antinuclear factors, anticytoplasmic factors, and rheumatoid factors About 10% of Hashimoto patients gave positive antinuclear or anticytoplasmic tests, and the incidence of low-titre anti-thyroglobulin antibodies was increased in S L E patients

Serum complement was diminished in S L E , Dr H A ELLIS (Birmingham) found, and might be increased in early active rheumatoid disease, although it fell later, especially when rheumatoid-factor titres were high

Dr R R A COOMBS (Cambridge) described the factor—immunoconglutinin—which appears in the serum of rabbits immunised with bacteria specifically agglutinated with antibody in the presence of complement, or indeed immunised with bacteria alone This factor, apparently an auto-antibody to complement, can be detected in the serum in many human infections, but is increased also in rheumatoid arthritis

Dr R G WHITE (London) described the use of immunofluorescent methods to locate γ-globulin intracellularly in the plasma-cell series in the medullary tissue of lymph-nodes, and in their germinal centres He drew attention to the follicular hyperplasia and plasma-cell proliferation found in rheumatoid lymph-nodes

The significance of the rheumatoid serum factors was discussed by Dr J BALL (Manchester), who said that the rheumatoid macroglobulin factor for rabbit globulin could be detected in about 40% of adults, and in significant titre in 2–5% of Northern Europeans Positive tests were found (apart from rheumatoid arthritis) in a significant proportion of cases of S L E , systemic sclerosis, digital arteritis, and Sjogren's syndrome About 35% of positive tests in a random sample were associated with clinically detectable disease

Dr C L GREENBURY (Stoke Mandeville) described quantitative experiments using radio-iodine to label rheumatoid factor or antibody, which indicated that the amount of factor removable by repeated absorption from a given serum varied according to the degree of sensitisation of the absorbing red cells

Dr B CRUIKSHANK (Glasgow) doubted whether γ-globulin was significant in the ætiology of rheumatoid disease Only a minority of the plasma-cells in the inflammatory lesions of rheumatoid tissue had been shown to contain either 7S or 19S γ-globulin He had found histological changes in synovial tissue in ankylosing spondylitis essentially similar to those in rheumatoid arthritis, but associated neither with serum rheumatoid factor nor with increased serum-γ-globulin. In agammaglobulinæmic rheumatoid disease, too, plasma-cells were virtually absent from the inflammatory lesions.

Dr J. N. McCormick (Stoke Mandeville) had used partially denatured human γ-globulin labelled with fluorescein to detect rheumatoid factor in unfixed frozen biopsy material from rheumatoid arthritis. The cells containing the factor were mainly plasma-cells, and were most numerous in rheumatoid synovial tissue. The globulin of the germinal centres, although abundant, appeared to contain very little rheumatoid factor.

Fluorescence methods of locating tissue antigens (using fluorescein and rhodamine conjugates) were also described by Dr G. Scott (Stoke Mandeville). Using anti-glomerulus and antisynovial-membrane conjugates, he had defined three components of human connective tissue by immunohistochemical staining.

Dr W. R. M. Alexander (Edinburgh) had found that synovial fluid from rheumatoid-arthritis patients injected intradermally in other patients or controls, often gave rise to a delayed skin reaction, apparently of the Mantoux type. The active factor, a γ-globulin, was very unstable, and usually did not cause a reaction in the donor's own skin.

Discussing his experience with antinuclear serum factor as revealed by the fluorescent-antibody method, Dr D. M. Weir (Taplow) said that the factor was almost invariably present in S.L.E., but was also found in rheumatoid arthritis, discoid lupus, and some other related conditions, although much less frequently and usually in lower titre. He described laboratory investigations on the nature of the antigen(s) reacting with the serum factor.

Dr G. J. Friou (Yale) had studied antinuclear factor using fluorescent and radioactive labelled antihuman globulin with whole nuclei, and nucleoprotein, as antigens.

Dr W. Hijmans (Leiden) regarded the L.E. cell factor as an antibody against nuclear material, and described quantitative precipitin studies between desoxyribosenucleic acid and serum, and complement-fixation studies with histone. He gave reasons for not considering the serum factor as pathogenic.

Dr E. J. Holborow (Taplow) considered the antigenic possibilities of the polysaccharides of connective tissue. He outlined natural and experimental methods of enhancing antigenicity of polysaccharides and drew attention to the lack of knowledge of whether they could take part in hypersensitivity reactions.

Medicine and the Law

The New Criminal Justice Bill

This Bill deals mainly with offenders under 21. Its main objects are to make wider provision for the use of borstal training and of detention centres in dealing with young offenders, to discontinue short sentences of imprisonment as more detention centres become available, and to extend the provision of compulsory aftercare. Changes are also proposed in the law relating to approved schools.

Part I remodels the custodial forms of treatment for young offenders. No new forms of treatment are proposed, but existing methods, particularly borstal training and detention centres, are extended to more offenders. Imprisonment will eventually be restricted to cases where no other sentence is appropriate. The new scheme depends on the provision of more borstals and more detention centres, and will be introduced by stages as the additional institutions are ready.

Borstal Training

The minimum age for a sentence of borstal training is lowered from 16 to 15 and the court will be able to pass such a sentence whenever they think it expedient that the offender should be detained for training for not less than six months. But if an offender is under 17, the court, before passing a borstal sentence, must decide that no other method of dealing with him is appropriate. The maximum term of borstal training is reduced from three years to two years and the minimum term from nine months to six months.

Imprisonment

The imprisonment of young offenders is restricted to sentences of not more than six months or long sentences of three years or more (except for some offenders who have already been in prison or a borstal). Short sentences of imprisonment are to be abolished by stages as more detention centres become available. Imprisonment of offenders under 17 is abolished, but the power of the higher courts to sentence children and young persons found guilty of grave crimes to detention as the Secretary of State may direct is extended. At present, this power is confined to offences of attempted murder, manslaughter, or wounding with intent to do grievous bodily harm. The Bill extends it to include any offence for which an adult could receive a sentence of 14 years' imprisonment or more.

Detention Centres

Where the court decides that a short period of training is appropriate, the offender will be committed to a detention centre. For offenders until 17 dealt with by a magistrates' court, the period of detention will be a standard term of three months. The higher courts will have discretion to fix the period of detention within a minimum of three months and a maximum of six.

Approved Schools

The law about committal to an approved school is not altered, but the Bill provides that a boy or girl of not less than 15 can be removed temporarily from an approved school on a justice's warrant, if this is necessary to maintain discipline, to another approved school, a remand centre, or a remand home for up to twenty-eight days. Offenders who turn out to be unsuitable for approved-school training, but are likely to benefit from borstal training may, with the consent of the Secretary of State, be brought before a magistrates' court, which will have power to order their transfer to borstal.

Attendance Centres

The minimum age at which a child may be ordered to attend at an attendance centre is reduced from 12 years to 10.

Fines

New and, in general, higher limits are set to the fines that magistrates' courts may impose in respect of offences committed by children and young persons, and the obligation on a parent to pay damages of costs awarded against his child is extended to the payment of compensation for loss. Enforcement of fines will be by committal to a detention centre or a remand home for offenders under 17.

Compulsory Aftercare

This is usually undertaken by probation officers. It is extended for the first time to all offenders who are released from a detention centre (unless they were sent there for a default) and to some categories of people released from prison. The extension of compulsory aftercare to ex-prisoners will be introduced by stages. When it is completed it will include all sentences of four years or more whatever the age of the offender, all sentences of six months or more where the offender was under 26 at the start of the sentence, and all sentences of six months or more when the person has previously had a prison sentence of three months or more or a borstal sentence.

In England Now

A Running Commentary by Peripatetic Correspondents

ONCE again the Director-General's Exercise—this year named White Swan—gave us a programme packed with interest, a shop-window of ideas for the future. Some will be discarded, but others will bear fruit. I asked three very senior officers what was the biggest problem facing the Army Medical Services today. One said the acquisition of broader professional experience. Another said the recruitment of other ranks (and gave me an entertaining lecturette on how to do it). The third said transport, transport, and transport again. If you can transport the sick and wounded, quickly and shocklessly, over long distances to the medical centres, you can economise in medical manpower and equipment—and that appeals both to the operational commander, who wants to slim his administrative tail, and to the manpower planner, faced with a return to voluntary service after twenty years of conscription. Transport today and tomorrow means air transport (the day after tomorrow it may mean hovercraft or rockets) and the D.G. duly showed us long-range aircraft, the rotodyne, helicopters—the lot. A French general told us about the enormous use made of helicopters by the French army in Algeria. The six-year-old Algerian war has given the French more experience than any other nation of air evacuation, but he indicated that the French Army did not want to go on accumulating this experience.

We also saw the latest types of civil ambulance cars, some with bodies completely constructed of plastic reinforced with glass-fibre, which is strong, light, rustless, and never needs painting. Yet with road congestion getting worse every day, will not the local health authorities have to invest in helicopters? Let the R.A.M.C. show the way. At the Cambridge Hospital they could establish an accident centre, equipped with helicopters and aerial cameras, to serve the whole of the Aldershot district. The casualty department would be staffed with surgeons of the requisite experience, a helicopter-ambulance could be at the scene of an accident in a matter of minutes (even on bank holidays), and every accident could be photographed from the air. What a contribution such a unit could make to research into the causation, prevention, and treatment of road accidents!

An excellent curry—made with dehydrated ingredients and served in a hangar—revived our spirits after the cold of the airfield. We saw the impressive efforts which are being made to modernise and improve military medical equipment. The Plastic Age is dawning, and the reductions in total weight and bulk are nothing short of dramatic. The new lightweight medical panniers were demonstrated by an extremely smart Nigerian private who has won the Duke of Edinburgh's gold award.

I am not yet convinced of the value of the universal container—a lightweight room that can be carried by air and deposited on any little flat piece of ground. We saw it being used as an operating-theatre, as a pathology laboratory, as an advanced medical store, as a heatstroke centre, and as the examination and treatment room for a 10-bed medical reception station. Perhaps it was the sight of ten "patients" lying in bed in the pouring rain (were there not enough canvas roofs to go round?) that made me feel that further experiment in the design of tentage and supports is what is really needed. The School of Health gave us an admirably straightforward demonstration of ten basic health routines for the soldier, after which there was a bit of a barney about urine tests for paludrine.

The Exercise gets more like an international congress every year. None of the American officers would hazard a guess on the result of the Presidential election. Eminent officers from the Indian subcontinent spoke to me gloomily about the changed status of their 2000-year-old Maginot Line of the Himalayas. A Canadian officer told me that the integration of the Canadian Forces medical branches (which so bewitched our political mentors in the Select Committee on Estimates) had scarcely changed anything. Just at present, integration seems to be more urgently needed in certain political circles than anywhere else. At the Exercise supper a well-known authority on malaria prevention presided with patriarchal dignity over a table of pretty nursing officers, and somebody round the piano sang "I'm Dreaming of a White Swansong".

* * *

I am, I confess, a secret thinker, and one day in the rush-hour I caught myself at it again. Suppose a Neptunian scientist (people on Neptune are very large) knowing nothing about life on Earth were to hover over some of our greater cities, studying the traffic. He would notice that the multi-coloured shining particles which moved in certain natural channels appeared to obey certain laws. These laws, it is true, would not always be rigidly followed, they would be approximate, statistical, stochastic laws, similar to those of chemical kinetics and thermodynamics in our own scientific culture. He would observe, for example, that when a space appeared among a stream of particles, one of them would inevitably sooner or later move into the gap, so that the place left behind it could in turn be filled by another particle and so on, giving the overall effect of a sluggish wave-like forward motion. He might well postulate some kind of force, tending to move the particles by mutual pressure into regions of low population density. "Nature", he might aphoristically say to himself, "abhors a vacuum." Or he might notice that when the population-density was high, the noise-level also tended to be high, or there might be a relation between the average rate of the forward wave-motion and the density, or between the noise-level and the mean distance travelled without collision. In short, our Neptunian might soon build up a set of traffic laws akin to the gas laws of physics.

At this point in my meditations I stopped my forward wave-motion with something of a jolt, causing a transient sharp rise in the local noise-level. If a Neptunian were to look on us like that, would he be doing anything fundamentally different from what we do when we study the molecules of a gas? And would it ever occur to him that each one of those curious shiny particles, with their semi-random, semi-determinate motions, might contain a living, sentient, meditative being such as myself? Well, then, how about the gas molecules? Who might there not be inside them, I asked myself. And, do you know, the thought has bothered me since. After all, how do we know that an atom doesn't think of itself as ME? It's time somebody looked into the matter, in my opinion, because if we go on treating the atoms the way we do now, some day there'll be trouble.

* * *

We had a rotten trip back fom the States. Even the official log of the *Mauretania* described the conditions as "strong N'ly gale, very rough sea, very heavy N'ly swell". After long deferment of hope in successive arrivals at Cobh and Le Havre, we reached Southampton. I telephoned my wife and arranged for her to meet me in Newcastle at 7 A.M. The boat train took me to London, where I boarded the sleeper at King's Cross.

I woke up at 6 A.M., and reflected that this was the ninth day since leaving New York, but that I would be home in an hour. The attendant brought tea. I remarked that it seemed very quiet outside. "Yes, Sir," he said, "I'm afraid we're still in Northallerton, and we're an hour behind time. I'm just going to find out what's the matter." He was back in a few minutes to say "It seems, Sir, that the fire went out. They're busy trying to get it going again."

Not even the rich new expletives that I had learnt in America were of any use to me. I was speechless.

* * *

Our quiet, shy, third-year medical student disappeared behind the screens to examine a middle-aged blonde patient. All was well for a few minutes as his examination proceeded, but suddenly the quiet of the ward was shattered by scream upon scream and the words "I wouldn't even let my husband do that." The student emerged blushing furiously to explain to

Sister, who advanced in a menacing way, that he had only been eliciting the patient's plantar responses

* * *

A long time ago I made the mistake of learning how to use a desk calculating machine It was useful to me at the time, because I do not like doing sums and it was much nicer to have a thing like a typewriter to do them for me But it got me a reputation which did me no good at all, and I became known as the department's statistician (unpaid and quite extra to my proper jobs) and general calculator-man I have never been strongminded enough either to repudiate the status or to insist on people learning to do sums for themselves Now, to put the seal on my position, I have been sent on a computer course because " it might be useful if you get the know-how "

I must say the computer people were very nice and friendly to us (I could be friendly too, if someone wanted to learn from me how to use my little desk machine instead of wanting it done for him) Their machine was friendly too, a bit dour the first time we called on him, but then he was said to have a pain in his inside, and an appreciable smell of beer in his neighbourhood suggested that he knew how to look after himself when out of sorts Later he was in splendid form, inverting a large matrix and playing a happy tune on his hooter to announce progress after each thousandth sum or so—i e , a brisk toodleoodleoo, with a thousand to each " ooo " Our job, it appeared, was to learn a language which he could understand well enough to translate into his own dialect, and presently we were writing

```
A = 2
B = 2
A = AB
PRINT (A)
```

which seemed a funny way of putting 2 × 2 and downright wrong algebra But presently we grasped bits of it, and were happily composing letters to the supermachine and even typing them ourselves on the teleprinter which makes the only kind of signs he is really interested in reading

By the end of the course the real mathematicians had become obvious, while some amateurs had fallen by the wayside altogether This was not quite my fate, but I did get a bit mixed up about what was computer-work and what was not I wandered into the unit's common room and was interested to find *The Times* with the crossword only half done The supermachine couldn't have been too slow to finish, it was nice to think that in some ways he might have been too stupid But then computers are apt to have a streak of stupidity look at me still doing the department's sums for them I never thought that this course would show me that what I have most in common with supermachines is a willing nature

* * *

Aunt Pash must be one of my oldest patients She is said to be 93, has one eye, and a colostomy She lost her eye in " one of they girlish pranks " I am not sure what she means by that, but knowing Aunt Pash, I fear the worst I usually visit her hut on the beach when I am in that part of the district, but three times lately it has been empty, and neighbours told me that Pash was visiting However, the last time I was up the Bay, she was home again, and her hut was, as ever, chaotic with spinning and quilting This time there were no tales of her girlhood—the more lurid of which always ended with 'Ah, my dear, the tales I could tell'ee, the tales I could tell ee " No, she had been out gallivanting, and mightily she had enjoyed herself A distant cousin had moved house, and she had gone to help Now it may not be remarkable for an elderly lady to hold very small pieces of china at a housemoving, but in Newfoundland housemoving literally means house-moving The house is taken from its foundation, hauled down to the edge of the water, floated on to a raft, and towed to its new site Once there it is dragged out and hauled into position It is a backbreaking job, and all hands are needed on the lines This is what Aunt Pash had been doing on her holiday Later I was told that she had worked as hard as anyone and cussed better than most I don t doubt it at all

Letters to the Editor

FUTURE ORGANISATION OF PATHOLOGISTS

SIR,—Since with the approach of voting-day for pathologists, past-presidents of the Association of Clinical Pathologists have written to press the advantages of the recent " offer " of the Royal College of Physicians, I write to point to one important fact and event in the history of the Association that has been omitted from recent discussion and documents

The Association of Clinical Pathologists became incorporated on Feb 12, 1956 This was the culmination of the labours of a devoted secretary and had been pursued with enthusiasm by presidents, officers, and council, and the members and all knew that this was the initial stage in the formation of a new and independent college

What is it, therefore, that has caused presidents, officers, and council now so eagerly to favour " the present generous and unequivocal terms " of the recent offer of the Royal College of Physicians ?

That a diploma of membership of a division or faculty of a Royal college would be an almost immediate result of acceptance of the offer is certain, and this would meet one of the needs of pathologists without any great effort—merely the subscription of foundation membership, or examination and membership fees But the status that this diploma might confer would be somewhat reduced by the inferiority attaching to a division or faculty (That a faculty is regarded as inferior is witnessed by the current action of a most ancient medical faculty that seeks by legislation to alter its title to Royal College of Physicians and Surgeons of Glasgow) Surely, the seniors in the Association are not unaware of this implication of inferiority which is not disguised by the use of the term division Why is it therefore that they advise a " short-cut " when the Association has progressed to incorporation unaided ? Everyone knows that a new and independent college may require a few years to have its diploma of membership recognised, everyone knows that a new college is not founded and nurtured without great effort and equally great sacrifice Those who earnestly and sincerely consider that an independent college should be the heritage of our registrars, and in turn their registrars, would work willingly and make sacrifices Is it that in the remaining years of their working lifetime the seniors would rather they held high office and examinership in a subsidiary faculty (of which they are fellows through being fellows of the parent college) than be concerned with great efforts the fruits of which would be enjoyed by posterity and not by themselves ? Or, to put it at a higher level, is it that the senior pathologists who are fellows of the Royal College of Physicians are using their influence to secure to this college, at the time of rebuilding, and for a long time, revenue from the pathologists that in the first instance might amount to around £25,000 ?

London, N 18 J F HEGGIE

SIR,—Dr Joan Taylor and Professor Pulvertaft are two of my oldest friends, but I am bound to tell them that most of their letter of Nov 5 is rubbish

Professor Pulvertaft has had much experience in the appointment of pathologists Has he ever found the absence of a specific higher qualification a handicap ? And if so, how often ? (In this debate a few quantitative statements will be refreshing) He makes appointments, as everyone else does, on the confidential advice of his colleagues and on his own judgment If he has made an occasional mistake I have little doubt that it has been when the flutterings of his warm heart have silenced the warnings of his cool head In our lifetime it has been characteristic of pathology—more, I think, than of any other branch of medicine—that it has drawn its adepts from a wide variety of sources the preclinical sciences, public health, and general practice have all contributed colleagues whom we respect There have been those pathologists who combined the humblest medical qualifications with fellowship of the Royal Society It is one of the weaknesses of the N H S that it is more difficult than it was to change from one specialised branch to another To add any degree or diploma which makes the entry into pathology more difficult or more rigid can only impoverish the science

"Academic centre" is, I suppose, looking-glass language for a college or faculty The adjective is an unusual one to apply to any existing body of this kind except, perhaps, the Royal College of Surgeons As for "a body to speak for pathologists", things have come to a pretty pass if Dr Taylor and Professor Pulvertaft are no longer able to speak for themselves To whom is this body to speak and about what? And who on earth would be able to speak for such a disorderly mob of individualists as we are?

In all this interminable debate the talk has always been of examinations and diplomas but seldom of training Is it not time that we abandoned this babu attitude? The Doctor and the Professor and I all learned pathology in the bad old way, picking up knowledge and experience as we could, piecemeal and without a plan The example of the course for the diploma in bacteriology has shown that a more systematic training is not only possible but desirable I see no reason why the same methods should not be applied to other branches of pathology if some university will give them a trial

Hoccombe, Somerset J A Boycott

Sir,—For Dr Joan Taylor and Professor Pulvertaft I have the greatest admiration and respect, but their idea of an academic centre for pathology in London seems completely out of touch with the ideas of those of us who work some distance from London

The higher qualification and the body to speak for pathologists can be achieved at a very small cost Dr O'Gorman (Nov 5) is rightly daunted by the cost of a building, but what pathologist outside London is going to use such a building?

For meetings, the Pathological Society and the Association of Clinical Pathologists have been able to enjoy the hospitality of numerous bodies all over the country The College of Pathologists could do likewise

Why should not the College of Pathologists start in a small way like the Royal College of Obstetricians and Gynæcologists?

As for withdrawing, as Dr O'Gorman suggests once we are in the Royal College of Physicians it will be impossible to withdraw from that body without its permission The constitution of that body is authoritarian, and it would be unreasonable to expect permission to withdraw to be granted, as G G implies (Nov 5, p 1025)

No, Sir! The only solution appears to be the logical conclusion of Peter Davey's argument He says that the physicians are notable Greek scholars They therefore know that a pathologist is a man who studies disease Their work is therefore pathology, not physic, which is the study of Nature

Let them show their greatness by changing their name to the Royal College of Pathologists We will then join in with them, so possibly will the other Royal Colleges! (Or am I optimistic?) We shall then have a body able to speak for the whole of Medicine

The alternative more likely to be acceptable is for the pathologists to have their own College, and for all the medical colleges, faculties, associations, and societies to join together to form an Academy of Medicine for that purpose

Mumbles, Swansea H C M Walton

Sir,—As an ordinary pathologist of a very peripheral hospital, may I support the plea of Dr Joan Taylor and Professor Pulvertaft for a vote in favour of the division of pathology within the Royal College of Physicians I started this year firmly in favour of an independent college and, because of the accident that it was my turn to be branch president, found myself defending this view on behalf of the North of England branch at a special meeting of the council of the Association of Clinical Pathologists held in February Because of this I subsequently had quite a long exchange of views with various members of the council, and have since become convinced that a division within the Royal College of Physicians will meet our needs

In the Widdicombe File, G G discusses the various obstacles in the way of an independent college and shows how they might be overcome, but he does not mention the greatest obstacle of all This is that the great majority of the leaders of our specialty do not favour the establishment of an independent college at the present time, but, in all sincerity, prefer the R C P solution It seems to me that it is possible and right for the main body politic of the Association of Clinical Pathologists to stop—if it so wishes—its leaders from going a certain way, but more than this is not possible The real issue in the forthcoming poll therefore is not between the R C P and an independent college but between the R C P and nothing at all for many years to come With the Royal Commission finished, the next ten years may be all-important in shaping the future pattern of British medicine, and it will be bad for both medicine and ourselves if during this time we alone among the major specialties have no official organisation

Northallerton P N Coleman

Sir,—Discussions on the future of clinical pathology have assumed that it has a future in the form we know today The supporters of a College of Clinical Pathologists ought to discuss this assumption and have not done so, association with the Royal College of Physicians involves considerably less mortgage of the future

We are not endowed with the gift of prophecy Twenty-five years ago few would have envisaged the position that clinical pathology enjoys today To assume that the present pattern will exist unchanged in 1985 is to make an improbable assumption Two branches (hæmatology and chemical pathology) are growing rapidly and show signs of passing out of the ken both of the general physician and of the clinical pathologist Hæmatology is already well on the way to becoming a subspecialty of internal medicine More slowly, chemical pathology is going the same way, the advent of automation, lessening as it must preoccupation with technique, will accentuate this trend Of the other branches of clinical pathology, hospital bacteriology is being divided more and more between the specialists in hygiene and therapeutics Remains pathology proper, the practitioners of which have always had a well-defined subject which does not take them to the bedside nor make them primarily technicians, it is probably the branch of pathology destined to change the least It seems at least unlikely that most of the subject-matters of clinical pathology will remain in the hands of a group called clinical pathologists and a College of Clinical Pathologists, if established, could become another South Sea House and an obstacle to progress

For reasons set out by Dr Joan Taylor and Professor Pulvertaft present action is needed such action should leave the future uncommitted as far as possible Association with the Royal College of Physicians is the only logical course

Sheffield ARTHUR JORDAN

⁂ A letter from the Widdicombe File appears on p 1094 —ED L

USE OF BRL 1241

SIR,—Dr Novick's letter (Oct 29) covers well-trodden ground and adds little except speculation to what we already know By now several thousand strains of *Staphylococcus pyogenes* have been tested, and so far no "celbeninase"-producing organisms have been found This suggests that they are rare if they exist at all, and are considerably rarer than penicillinase-producers were at the time of the introduction of penicillin On the other hand we are all agreed that bacteria often yield mutants which bypass the injurious effects of a chemical agent in some way other than destroying the drug This is an alternative and more common method of developing resistance to an antibiotic In the case of penicillin such mutants can readily be obtained by selection in the laboratory, but have not been shown to be the cause of lesions in man Thus of the two kinds of resistance to penicillin only the one based on the destruction of the drug by an enzyme is clinically important Since 'Celbenin' is a derivative of penicillin having in all probability essentially the same mode of action it would be reasonable to expect that resistant mutants (non-"celbeninase") might also lack pathogenicity, even though retaining coagulase and other characters However, whether this expectation is unfounded, and strains *do* exist which retain sufficient virulence to be of clinical importance and in addition are endowed with sufficient communicability to occupy the biological space in hospitals, can be determined only by carefully controlled clinical observations

The demonstration of celbenin-resistant staphylococcal mutants was probable on general grounds and would be expected to follow the pattern of multiple steps of mutation seen with penicillin, each step resulting in greater resistance As the serum levels obtainable with celbenin at present are more restricted than with penicillin, it is conceivable that first or second step mutants could acquire sufficient resistance in vivo to escape therapeutic action, and yet retain pathogenicity With spraying, however, this is less likely to occur since much higher concentrations can be achieved locally and the mutants succumb to the higher doses of the drug Resistant mutants are not man-made, only selected, and on speculative ground at any rate are more likely to result from therapeutic use than from spraying

Dr Novick says that " it is conceivable that the method might be used indefinitely without unfortunate consequences, and it could be argued that the risk involved is acceptable in view of the advantages This risk must, however, be assessed in the light of the history of the fight against the staphylococcus " We submit that this is precisely what we did—bearing in mind the fundamental clinical problem of penicillin resistance

It must be admitted that a complete victory along these lines is perhaps not in sight, but that should not make one jettison a line of research on theoretical grounds The spraying of carbolic by Lister did not altogether banish hospital gangrene, but while it was in use undoubtedly saved a great number of lives We believe that the discovery of celbenin by the Beecham group was a milestone in the history of antimicrobial agents and will certainly lead to new and powerful drugs in the future In the meantime experiments with spraying should continue until their value is proved or their risk demonstrated on a factual basis

PROGNOSIS AND ANTICOAGULANT PROPHYLAXIS AFTER CORONARY OCCLUSION

SIR,—In their very valuable article of Nov 5 Professor McMichael and Dr Parry suggest that the unusually good 5-year survival-rate of doctors after cardiac infarction is because "no doubt they can take greater care of themselves and avoid undue physical strain" It is surprising that the authors, who are so rightly critical of loose thinking and imprecision in others, should make such a dubious statement What does "taking care of themselves" mean? And what evidence is there that "avoiding undue physical strain" prevents further infarcts?

I submit that a more plausible explanation of the apparent good prognosis in doctors is that their *minor* cardiac infarcts are more often diagnosed than are the minor infarcts of the laity, the symptoms of which are apt to be attributed to "*indigestion*"

Farnham, Surrey JOHN W TODD

POSTPARTUM PRE-ECLAMPSIA

SIR,—I have read Flight-Lieutenant McFadyen's article of Nov 5 and should like to make the following comments

I have already shown [1–4] that the contracting postpartum uterus provokes renal ischæmia (which incidentally ergometrine might heighten, and this is evident in all the cases reported), that renal ischæmia is responsible for hypertension, œdema, and albuminuria, that hydramnios is an agent provocateur of renal ischæmia (main case), that pre-eclampsia is to be suspected with even minimal signs of the syndrome (main case), that there are many conditions that post partum can masquerade as pre-eclampsia (case 2 certainly being one in point) In fact his case-histories, if interpreted in the light of the data I have provided, amply support the thesis that the uterus resisting tension, which it does post partum also, provokes the uterorenal reflex from which the signs of toxæmia can all stem

Further I have collected sufficient evidence [5 6] to show that the symptomatology of toxæmia is not comparable to Cushing's syndrome, that as toxæmia mounts so do the corticoids decline, that corticotrophin (A C T H) when given experimentally in human pregnancy does not provoke the syndrome, that eclampsia does occur when the adrenals have been previously extirpated, and that the placental production of corticoids is very small in contrast to that of the adrenals

May I also draw attention to two very important data?

---

1 Sophian J Toxæmia of Pregnancy London 1953
2 Sophian, J *Excerpta Med* 1958 sec x, 2 no 1
3 Sophian J *Lancet* 1960 i 1351

5 Sophian J *Lancet* 1958, i 434
6 Sophian J *Amer J Obstet Gynec* 1954 68, 733

Garrod[7] found that there was an immediate increase in glomerular filtration-rate (G F R) provoked by cortisone experimentally, while there is incontrovertible evidence to show that G F R is much decreased in toxæmia[1]

It would profit obstetricians to study the renal problem deeply To this end may I congratulate you on your enterprise in publishing an account (Sept 17) of the 1st International Congress of Nephrology at Evian, excellently compiled by Professor de Wardener

Worthing, Sussex
JOHN SOPHIAN

CHEMOTHERAPY IN CHRONIC BRONCHITIS

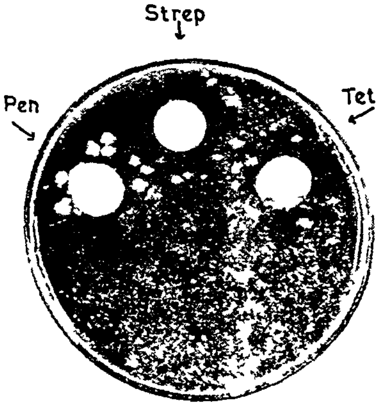
SIR,—The paper by Dr Pridie and his colleagues (Oct 1) and the letter by Dr Aspin and Dr Howells (Oct 15) regarding long-term treatment of chronic bronchitis with antibiotics contain findings somewhat at variance with our own The minimum recommended dose of tetracycline or oxytetracycline for the continuous treatment of chronic bronchitis is 0 5 g daily, but we found 1 g per day to be the minimum satisfactory dose A smaller dose is in our view unlikely to be effective in the treatment of the majority of established cases of chronic bronchitis It does not seem to be a fair test of the efficacy of therapy to use a smaller and relatively ineffective dose With a dose of 1 g daily we have shown that the side-effects are much less significant to the patients than the incapacity which results from acute exacerbations of the disease in untreated cases

Further, the fullest bacteriological information can be obtained only by examining serial specimens of sputum freshly obtained from the patient We have shown that the correlation of the findings obtained from a single isolated specimen of sputum with the clinical state of the patients is poor The mere isolation of organisms not normally found in the respiratory tract, notably the coliform group, had little or no association with the clinical state of the patients, none of whom was treated in hospital

Departments of Infectious Diseases
and Bacteriology
City Hospital, Edinburgh
J McC MURDOCH
J C GOULD

SIR,—I note the letter by Dr Aspin and Dr Howells with particular interest because I have recently been associated with a clinical trial in chronic bronchitis to assess the value of vaccine therapy in contrast to the normal procedures of chemotherapy and antibiotic treatment

During this trial samples of sputum from some 50 patients were examined and we were particularly struck by the suppression of the normal flora with stimulation of growth of coliforms in vitro, using antibiotic-disc technique (see fig)



Stimulation of growth of *Klebsiella pneumoniæ* by antibiotics in sputum-culture from case of chronic bronchitis

This has led us to believe, as your correspondents suggest, that in treating chronic bronchitis intermittently with antibiotics the suppression of the usual flora may lead to consequent increased growth of the coliform organism

We have therefore persisted in our researches to determine what help vaccine therapy could give

We have been using a polyvalent oral vaccine for this purpose, and have had a great deal of assistance from general-practitioner colleagues in this project Should any of your readers be interested in helping us undertake a larger scale trial we should be grateful to hear from them and supply them with the necessary vaccine

R E DEREK LEIGH

SURGICAL REMOVAL OF BRANCHIAL SINUS

SIR,—I should like to congratulate Mr Allan Small on his article of Oct 22 Whether the condition is fistula or sinus is still a debatable point, but at The Hospital for Sick Children, Great Ormond Street, there have been many true fistulæ

This has been proved by the injection of dye into the track and its detection in the pharynx even before operation

The only point in the article that causes some concern is that related to thyroglossal cysts and their tracks I presume that Mr Small implies that the more difficult part of the dissection includes the excision of part of the hyoid bone and the very careful removal of the proximal part of the track as far as the foramen cæcum

If this point is not strongly stressed I am sure that the recurrence-rate in this condition will increase and lead to many more difficult secondary operations

The Hospital for Sick Children,
London, W C 1
S J COHEN

SIGNIFICANCE AND CLASSIFICATION OF FAT-EMBOLISM

SIR,—In his important paper of Oct 15 Dr Sevitt concludes that pulmonary fat-embolism produces no significant ill-effects in previously healthy subjects, and that it does not cause death even in those suffering from shock or blood-loss The validity or otherwise of this conclusion is of great practical importance, for it must influence the rationale of treatment If pulmonary fat-embolism is harmless then the thing to be avoided at all cost is systemic spread of the emboli, for there is general agreement that systemic fat-embolism is potentially a very serious condition Acting on this belief, some German workers[1–3] have practised a prophylactic regime whose object is the maintenance of " controlled hypotension ", in order to reduce the risk of pulmonary fat-emboli being forced through into the systemic circulation

I am less certain than Dr Sevitt that pulmonary fat-embolism is innocuous when very severe or when associated with shock or hæmorrhage The absence of a *characteristic* clinical symptom-complex does not necessarily mean that the condition is free from clinical manifestations of any sort It must be conceded that intravenous injection of fat in animals may produce severe effects and even death, although the lethal dose may be considered high there is a considerable species difference in tolerance—the dog, for example, is much more tolerant than the rabbit[4 5]—and results should not be applied uncritically to man Furthermore, there is abundant evidence that processes such as bleeding or the induction of tourniquet shock much reduce the tolerance of animals to intravenously injected fat[4–8] The contrary finding of Armin and Grant[9] stands alone and

9 Armin J , Grant, R T *Clin Sci* 1951, 10 441

may be attributable to the very small dosage which they employed

Degrees of pulmonary fat-embolism much more severe than that defined by Armin and Grant as " gross " are not uncommon in man [10] Certainly these are the cases in which fat-emboli are most likely to spread systemically, but it is also in such cases that changes due to pulmonary embolisation are liable to be erroneously ascribed to the effects of systemic involvement Although the pathological changes in the lungs—œdema, congestion, and hæmorrhage—are not in any way specific this does not exclude a causal relationship, and in any event the effects of pulmonary fat-embolism may be circulatory as well as respiratory [11] In my experience a predominantly intra-arteriolar and intra-arterial distribution of fat emboli in the lungs is often associated with a short survival time and an absence of systemic embolisation [10] Any system of grading the severity of embolisation should take cognisance of the size and situation of the emboli as well as of their numbers

While the arrest of fat emboli in the pulmonary vasculature undoubtedly protects the systemic circulation it can hardly be regarded as other than a pathological event, I submit that pulmonary fat-embolism should not be entirely discounted as a cause of illness and even death

TRIGEMINAL NEURALGIA

SIR,—Professor Dechaume has very kindly sent me two papers [12] [13] in which he cites the temporomandibular joint as a potential source of true trigeminal neuralgia I was unaware of these papers when I wrote my letter of Oct 1, and I apologise for that omission Professor Dechaume suggests a method of treatment which is new to me—namely, that the sympathetic enervation of the joint is an effective means of breaking into the vicious circle of effect aggravating cause

Colchester

MICHAEL FROST

NICOTINIC ACID IN ISCHÆMIC DISEASE

SIR,—Dr Archibald's criticism (Oct 8) of bus-drivers resuming their occupations after a coronary thrombosis is very pertinent, and it was only after very careful consideration that these drivers were allowed to go back to work Dr Archibald in effect poses the question " Should all patients who have had a coronary thrombosis be forbidden for that reason to drive a car ?" With the usual treatment, I should be inclined to say " yes ", but I would stress that there is a basic difference with the treatment described in my article of Sept 24

It is interesting that Hunter [14] has described results after nicotinic-acid therapy comparable with my own, except that his dosage is smaller, and he concludes that the improvement in angina is maintained so long as treatment is continued, and that angina gradually returns when treatment is stopped This is in accord with my experience over the fifteen years I have used this treatment, both after infarction and in angina, and it is for this reason that I came to the considered conclusion that ischæmic disease is probably a deficiency disease mainly of nicotinic acid, possibly also of pyridoxine (which forms a coenzyme mediating transaminase reactions and which is probably involved in the enzyme, glutamic-oxaloacetic transaminase) According to this concept, nicotinic acid is a physiological corrective of ischæmic disease

The first patient cited, who is an insurance agent, tells me he makes more than 100 calls a day in his car, and he has done this now for a long time The bus-drivers are seen and examined twice a quarter

Rothwell Haigh,
near Leeds

C E GOLDSBOROUGH

THE VERY DEAF CHILD

SIR,—The complaint of this school, which admits many children who have received various forms of home training, an important aspect of the work of most audiology clinics, is that the period before entry to school for most of them has been inadequately used

Of the present roll of 40 children, 32 have had preschool help of this kind, varying in length from six months to four years 30 of these children had hearing-aids issued by the clinics 2 were deemed too deaf to profit from an aid, though the parents of 1 bought a commercial model

Of the 31 with hearing-aids, only 4, however, were wearing them correctly—i e , continuously and at the right setting with an ear-mould which fitted sufficiently well to enable the necessary volume to be reached without acoustic feedback

At the moment of writing, 21 of the 31 children are wearing their aids properly both in and out of school with corresponding gains in speech improvement and language development Included in the 10 children who do not reach at home the standard of " hearing-aid usage " expected and obtained from them in school are all the 6 children with multiple handicaps The remaining 4 are among our most recent admissions

The fact that so many of these non-hearing-aid-users were trained within a relatively short space to regard their aids as an indispensable ally in their fight against deafness, and not as a barely tolerable encumbrance underlines the need to examine the weaknesses of a form of training which permits so much waste of valuable auditory training time

No teacher of the deaf, as far as I am aware, disputes the immense value of parent guidance and help to the children, particularly during the period between the diagnosis of deafness and the age of 2–3 years Many of us, however, believe that a special nursery school, fully equipped and staffed, where parents are free to come and go and take part in our work, where visiting otologists and psychologists can see the children in surroundings more appropriate than the clinical situation found in audiology units, offers not only the well-known advantages of nursery-school training but also permits conditions suitable for full-time educational and audiological help of the kind appropriate to the children's individual needs In addition, because continuous observation under controlled conditions is possible, it allows a more rapid and accurate assessment of the children's abilities and the nature and degree of their hearing loss, and enables future school placement to be considered on a better-informed basis

Such a special school should cooperate with local hearing schools for selected activities where the children of both schools can meet and play and, under skilled supervision, work with one another (This is not difficult to arrange—we do, in fact, work with 3 nearby hearing schools in Woodford in this way)

Miss Whetnall (Oct 15) has referred to the work of Wedenberg [1] who, for the initial period of auditory training, applies a live voice to the meatus of the deaf child without the use of an aid Unfortunately, she omitted to say that Wedenberg himself found that the best subjects for auditory training were the " *gifted children* (my italics) from groups 1a to 2a " (*i e*, children with considerable hearing for the important low frequencies, about 50 db at 250 and 500 cycles) and that children with much less hearing for low frequencies (groups 1b and 2b) were " difficult subjects even when their intelligence is high "

Of the children here for whom we have reliable audiograms 6 come within Wedenberg's groups 1a and 2a and of these 2 only are of above average intelligence

Even more significant is the fact that we are able to train children who Wedenberg found " difficult "—i e , the 1b and

POTASSIUM IN THE TREATMENT OF CHOLERA

SIR,—In their article last week Dr Watten and Dr Phillips suggest that in the treatment of acutely ill patients 10 mEq (7 5 g) of potassium chloride should be added to 1 litre of saline solution The amount in grammes should read *0 75* This is no doubt a slip, but it is an important one Owing to the danger that this may be overlooked, libraries might consider making the correction on the article itself

ADMINISTRATION IN MENTAL HOSPITALS

SIR,—With great respect, I wonder whether Dr Kidd (Oct 29) has really found the ideal solution to the problem of medical administration in mental hospitals

As a medical superintendent, before the advent of the National Health Service and since, I have been trying to find the ideal relationship between the holder of that office and his senior colleagues for thirteen years, but have not succeeded yet, although I do not give up hope

We have worked a 3-team system here for ten years, and I support wholeheartedly the doctrine of full clinical freedom for all consultants, indeed, my consultant colleagues here have never complained to me of any interference with their work, but much tact and tolerance are needed on both sides if the hospital is to function smoothly as a corporate entity Dr Kidd tells us that he is responsible to his management committee for the efficiency of the medical work of the hospital How does he equate this personal responsibility with the " full responsibility " of his colleagues ?

One example will suffice How would he deal with a situation such as this, which could happen at almost any mental hospital, any day ? A fellow consultant admits, as an informal patient, an aggressive psychopath, who then rapes the small daughter of a hospital employee, resident on the estate I have been in office long enough to know that the Press, the general public, and indeed the management committee will look to one person only for an explanation, and that person is the unfortunate superintendent It will not help him to say that Dr So-and-So had " full responsibility "

The Mental Health Act has defined responsible medical officers as those in charge of the treatment of the patient Responsible to whom, and for what ? Does " treatment " include control of liberty, food, clothing, social and occupational activities, pocket money, and all the many other aspects of a patient's life ? If so, the result could be chaos with as many " systems " as there are consultants

The duties, responsibilities, and powers of medical superintendents have never been clearly defined No official guidance has been given, presumably in pursuance of the well-known technique of leaving decisions to the man on the spot, with the useful loophole of blaming him afterwards if trouble arises

Responsibility implies authority to take any necessary action, but the authority of the superintendent is vague in the extreme Now that consultants, rightly so, are undertaking greater responsibilities, the functions of the medical superintendent are more than ever in need of clarification This should be done as a matter of urgency, before there occurs some such trouble as that depicted above, with the inevitable recriminations which would follow

Superintendents have " carried the can " for a long time, but, in a changing world, it would be helpful to know something of its new contents

Bracebridge Heath Hospital,
near Lincoln
W A S FALLA

SIR,—Dr Kidd and his colleagues are to be congratulated on having accepted some of the principles without which a mental hospital continuing to have a medical superintendent can hardly be expected to function efficiently These are that the medical superintendent should do clinical work and do it on a basis of equality with his fellow consultants, without powers of interference in their work

I am afraid, however, that Dr Kidd's exposition of the medical superintendent's position in regard to administration involves apparent contradictions and several false or dubious premises, as exemplified by the suggestion that " as far as the hospital management committee is concerned he is answerable to them for the efficiency of the medical work of the hospital " I can only think that in this context " answerable " means " responsible " in which case the proposition is quite untenable A medical superintendent working on a basis of clinical equality with his fellow consultants and without powers of clinical interference cannot be " answerable " for the efficiency of the medical work of the hospital It is very relevant that the Mental Health Act, 1959, Memorandum on parts I, IV to VII and IX, paragraph 29, describes the " responsible medical officer " as " not responsible or answerable for the patient's treatment to any other doctor "

Dr Kidd, having listed various coordinating and facilitating functions of the medical superintendent, all of which, I suggest, can be done as well by the chairman of the medical advisory committee, goes on to say that such work can " perhaps be better done by a man who is permanently appointed to the office, because he has powers of decision and authority not available to an elected chairman of a medical staff committee " These powers and authority appear to derive from his being " officially recognised as responsible for medical organisation " This official recognition has the interesting—and highly undesirable—result that hospital management committees "have to take more notice of his monthly reports than the resolutions of medical advisory committees '

This is precisely the situation which consultants in many mental hospitals are no longer prepared to tolerate, especially in view of the fact that as from Nov 1 such hospitals will operate on the same basis as general hospitals All boards of governors of teaching hospitals and the management committees of most general hospitals recognise and " take notice " of their medical advisory committees as represented by an elected chairman Dr Kidd has made no case why management committees of mental hospitals should not do the same Such recognition should be based on the principle that the senior medical staff in any hospital have an equal and shared responsibility for reaching an agreed policy on all administrative matters affecting the hospital as a whole and that the essential administrative work of the medical superintendent or chairman of the medical advisory committee is to facilitate the carrying out of such agreed policy This may involve difficult negotiations with hospital management committee, regional hospital board, hospital officers, and others In such situations the

may be attributable to the very small dosage which they employed

---

[2] *ibid* p 19 (reference to the definition issued by the Conference of Executives of American Schools for the Deaf, 1937)

Degrees of pulmonary fat-embolism much more severe than that defined by Armin and Grant as " gross " are not uncommon in man[10] Certainly these are the cases in which fat-emboli are most likely to spread systemically, but it is also in such cases that changes due to pulmonary embolisation are liable to be erroneously ascribed to the effects of systemic involvement Although the pathological changes in the lungs—œdema, congestion, and hæmorrhage—are not in any way specific this does not exclude a causal relationship, and in any event the effects of pulmonary fat-embolism may be circulatory as well as respiratory[11] In my experience a predominantly intra-arteriolar and intra-arterial distribution of fat emboli in the lungs is often associated with a short survival time and an absence of systemic embolisation[10] Any system of grading the severity of embolisation should take cognisance of the size and situation of the emboli as well as of their numbers

While the arrest of fat emboli in the pulmonary vasculature undoubtedly protects the systemic circulation it can hardly be regarded as other than a pathological event, I submit that pulmonary fat-embolism should not be entirely discounted as a cause of illness and even death

MICHAEL FROST

NICOTINIC ACID IN ISCHÆMIC DISEASE

SIR,—Dr Archibald's criticism (Oct 8) of bus-drivers resuming their occupations after a coronary thrombosis is very pertinent, and it was only after very careful consideration that these drivers were allowed to go back to work Dr Archibald in effect poses the question " Should all patients who have had a coronary thrombosis be forbidden for that reason to drive a car ?" With the usual treatment, *I should be inclined to say " yes ", but I would* stress that there is a basic difference with the treatment described in my article of Sept 24

It is interesting that Hunter[14] has described results after nicotinic-acid therapy comparable with my own, except that his dosage is smaller, and he concludes that the improvement in angina is maintained so long as treatment is continued, and that angina gradually returns when treatment is stopped This is in accord with my experience over the fifteen years I have used this treatment, both after infarction and in angina, and it is for this reason that I came to the considered conclusion *that ischæmic disease is probably a deficiency disease mainly of* nicotinic acid, possibly also of pyridoxine (which forms a coenzyme mediating transaminase reactions and which is probably involved in the enzyme, glutamic-oxaloacetic transaminase) According to this concept, *nicotinic acid is a physiological corrective of ischæmic disease*

The first patient cited, who is an insurance agent, tells me he makes more than 100 calls a day in his car, and he has done this now for a long time The bus-drivers are seen and examined twice a quarter

C E GOLDSBOROUGH

THE VERY DEAF CHILD

SIR,—The complaint of this school, which admits many children who have received various forms of home training, an important aspect of the work of most audiology clinics, is that the period before entry to school for most of them has been inadequately used

Of the present roll of 40 children, 32 have had preschool help of this kind, varying in length from six months to four years 30 of these children had hearing-aids issued by the clinics 2 were deemed too deaf to profit from an aid, though the parents of 1 bought a commercial model

Of the 31 with hearing-aids, only 4, however, were wearing them correctly—i e , continuously and at the right setting with an ear-mould which fitted sufficiently well to enable the necessary volume to be reached without acoustic feedback

At the moment of writing, 21 of the 31 children are wearing their aids properly both in and out of school with corresponding gains in speech improvement and language development Included in the 10 children who do not reach at home the standard of " hearing-aid usage " expected and obtained from them in school are all the 6 children with multiple handicaps *The remaining 4 are among our most recent admissions*

The fact that so many of these non-hearing-aid-users were trained within a relatively short space to regard their aids as an indispensable ally in their fight against deafness, and not as a barely tolerable encumbrance underlines the need to examine the weaknesses of a form of training which permits so much waste of valuable auditory training time

No teacher of the deaf, as far as I am aware, disputes the immense value of parent guidance and help to the children, particularly during the period between the diagnosis of deafness and the age of 2–3 years Many of us, however, believe that a special nursery school, fully equipped and staffed, where parents are free to come and go and take part in our work, where visiting otologists and psychologists can see the children in surroundings more appropriate than the clinical situation found in audiology units, offers not only the well-known advantages of nursery-school training but also permits conditions suitable for full-time educational and audiological help of the kind appropriate to the children's individual needs In addition, because continuous observation under controlled conditions is possible, it allows a more rapid and accurate assessment of the children's abilities and the nature and degree of their hearing loss, and enables future school placement to be considered on a better-informed basis

Such a special school should cooperate with local hearing schools for selected activities where the children of both schools can meet and play and, under skilled supervision, work with one another (*This is not difficult to arrange*—we do, in fact, work with 3 nearby hearing schools in Woodford in this way)

Miss Whetnall (Oct 15) has referred to the work of Wedenberg[1] who, for the initial period of auditory training, applies a live voice to the meatus of the deaf child without the use of an aid Unfortunately, she omitted to say that Wedenberg himself found that the best subjects for auditory training were the "*gifted children* (my italics) from groups 1a to 2a" (i e , children with considerable hearing for the important low frequencies, about 50 db at 250 and 500 cycles) and that children with much less hearing for low frequencies (groups 1b and 2b) were " difficult subjects even when *their intelligence* is high "

Of the children here for whom we have reliable audiograms 6 come within Wedenberg's groups 1a and 2a and of these 2 only are of above average intelligence

Even more significant is the fact that we are able to train children who Wedenberg found " difficult '—i e , the 1b and

Hove

F V GRIFFITHS

RADIOCHEMICAL SYNTHESIS OF TRIIODOTHYRONINE

SIR,—Dr Deutsch (Sept 10) draws attention to the possible formation of ^{131}I-labelled triiodothyronine by the decay of a molecule of thyroxine containing two ^{131}I atoms, and, with this in mind, discusses the results of Gross and Pitt-Rivers [1-3] and of Braasch et al [4] His conclusions assume that in these experiments a substantial number of doubly labelled thyroxine molecules is present Certainly, as regards the work of Gross and Pitt-Rivers, this assumption is incorrect

The relative numbers of doubly and singly labelled molecules depend on the relative numbers of radioactive (^{131}I) and stable (^{127}I) atoms of iodine present The position can be more easily illustrated by referring to ^{131}I thyroxine synthesised in vitro by an exchange reaction In this material labelling can take place in only two atoms, those in the 3′,5′ positions, and not in all four atoms as in the material synthesised in vivo from ^{131}I iodide Mr Holloway and Mrs Pitt-Rivers (Oct 22) refer to the work of Tata [5] on decomposition products of ^{131}I-labelled thyroxine supplied by Abbott Laboratories Assuming that this materal is prepared by the method of Gleason,[6] and that it is not diluted with inactive thyroxine after preparation, we calculate, from the quoted maximum specific activity of 50 mC per mg thyroxine, that 1 mC of ^{131}I is associated with 6 5 µg of iodine in the 3′,5′ positions The weight of 1 mC of isotopically pure ^{131}I is 8×10^{-3} µg, and therefore in the 3′,5′ positions of this product 1 atom of ^{131}I is present to approximately 1000 atoms of ^{127}I This means that for every 2000 singly labelled molecules only 1 is doubly labelled No detectable amount of ^{131}I-labelled triiodothyronine is therefore likely to arise by the process postulated by Deutsch, and the fact that no ^{131}I-labelled triiodothyronine was detected in Tata's work gives us no information on the correctness or otherwise of Deutsch's postulate

The position regarding in-vivo syntheses is more complex Inactive iodine may be present in the so-called "carrier-free" ^{131}I iodide, and dilution with further inactive material may take place during transport in the body to the thyroid gland, and in the thyroid gland itself Before 1954, ^{131}I produced in Great Britain had a specific activity of about 1 mC per µg iodine this implies that about 1 in every 100 atoms of iodine present was radioactive It was this material that was used in the work of Gross and Pitt-Rivers Even had no further dilution taken place in the subjects the number of multiple (i e, double, triple, or quadruple) labelled molecules would be too small to yield a significant amount of ^{131}I-labelled triiodothyronines by decay (assuming that ^{131}I atoms are randomly distributed in the 4 positions of thyroxine, multiple-labelled molecules would form about 1 5% of the total labelled molecules)

The specific activity of ^{131}I produced in Great Britain has increased markedly since 1954 The Radiochemical Centre product is specified as being not less than 10 mC per µg iodine, and individual batches have given 20 mC per µg iodine this latter figure corresponds to 1 atom of ^{131}I in 6 atoms of iodine The proportion of ^{131}I atoms in fission product ^{131}I supplied by Oak Ridge is probably even higher Rupp et al [7] suggest 1 atom of ^{131}I to 1 atom of ^{129}I plus ^{127}I (^{129}I is sufficiently long lived to be considered stable) With material of such high specific activity any dilution with stable iodine in the body before thyroxine synthesis becomes specially important The factors determining the extent of such dilution are too complex for discussion other than by an expert in the field In general it seems reasonable to suppose that the extent of dilution will be relatively large In certain cases this may not be so, and ^{131}I-labelled triiodothyronine might arise in the manner postulated by Deutsch

Amersham

J C CHARLTON

PERITONEAL SPLASH A PHYSICAL SIGN

SIR,—Mr F G Smiddy (Oct 15) points out that this physical sign can be elicited only in the anæsthetised patient Many years ago, when I saw more patients with perforated peptic ulcer than I do now, I noticed that in some it was possible to detect a splash while percussing for free gas in the peritoneal cavity Light and careful percussion in the line of the right nipple with the patient prone will in many cases reveal the gas bubble which obliterates the band of dullness over the liver At the lower edge of the bubble the pleximeter finger detects a faint splash as the abdominal wall comes into contact with the surface of the fluid behind the bubble This sign is easily elicited when the perforation is large, there is much effusion in the peritoneal cavity, and the rigidity of the abdominal wall is less than board-like But then the diagnosis can more confidently be made by other means In the early case with a small hole, little effusion, and a rigid abdominal wall the sign is not easily elicited

I concluded that as a physical sign it was of little value, but when present it provided a comforting confirmation of the diagnosis

SIDE-EFFECTS OF LIBRIUM

SIR,—I read with close attention the correspondence that followed the letter by Dr Ingram and Dr Timbury (Oct 1) about the new drug methaminodiazepoxide ('Librium')

My mind was certainly imbued with that attitude of scepticism and circumspection favoured by your correspondents when I first prescribed these capsules for patients with anxiety states, since I had seen in recent years the much-vaunted advent of a glut of new drugs, the great majority of which were destined to find ere long a dusty tomb on some neglected shelf of the dispensary I soon came to the conclusion, however, that librium is of much value in the anxiety states Considerable benefit was obtained in some 5 out of 10 sufferers from morbid anxiety, a result which was the more impressive because not a few of them had previously had little or no relief from other calmative drugs—which clearly mitigates the influence of suggestion A large majority of those responding to the drug need take the relatively modest dose of 10 mg three times daily to gain relief from their emotional tension, disagreeable side-effects being exceptional in such

C GRIMSHAW

NEGATIVE ASSOCIATION OF ABO BLOOD-GROUPS WITH FRACTURED HIP

SIR,—In your issue of Aug 13, Dr Wiener said that Buchwalter had observed an excess of blood-group A in patients with fractured femurs We note that Buchwalter [1] has investigated the ABO blood-group distribution in 910 cases of fractured hips and found no statistical difference when compared with a control group We have examined a small series of patients who had been treated for fractured femoral necks at this hospital All these patients had been blood-grouped on admission as a matter of routine

TABLE I—ABO BLOOD-GROUP DISTRIBUTION

Group	Control series	Intertrochanteric fracture group	Other femoral neck fractures	Total test series
A	1906 *(32.3%)*	56 *(42.8%)*	73 *(33.5%)*	129 *(37.0%)*
B	637 *(10.8%)*	9 *(6.9%)*	22 *(10.1%)*	31 *(8.9%)*
AB	178 *(3.0%)*	2 *(1.5%)*	6 *(2.7%)*	8 *(2.3%)*
O	3177 *(53.9%)*	64 *(48.8%)*	117 *(53.7%)*	181 *(51.8%)*
Total	5898	131	218	349

TABLE II—DISTRIBUTION OF THE RHESUS FACTOR

Rhesus	Control series	Fracture series
Positive	344 *(80.6%)*	279 *(79.9%)*
Negative	83 *(19.4%)*	70 *(20.1%)*
Total	427	349

Table I shows the ABO groups of these 349 patients and those of the control series compiled from data from 5898 consecutive new donor registrations with the West of Scotland Regional Blood Transfusion Service The patients were further subdivided into intertrochanteric fractures and other femoral neck fractures This small series reveals that there is no significant difference in ABO blood-group distribution, although one may be impressed by the relatively high incidence of group A in the intertrochanteric fracture group, there is no statistical difference ($\chi^2 = 1.3$) Furthermore, table II shows that there is again no significant difference in the incidence of the rhesus factor in the fracture patients and those of a small control series of 427 donors

We wish to thank Dr I A Cook, Mr W Sillar, and Dr J Wallace for assistance, and Dr R A Robb for his statistical help

MODERN CLINICAL BIOCHEMISTRY

SIR,—Professor Cappell's presidential address (Oct 15) has called forth a prompt and explosive comment (Oct 29, p 985) from his biochemical colleague at the Western Infirmary

As a biochemist, Dr Hendry is naturally most concerned with Professor Cappell's assessment of the position of chemical pathology in the framework of clinical pathology, and there can be little doubt that he has voiced the feelings of many of the medical and non-medical biochemists who have entered or considered entering the hospital laboratory service These feelings are clearly expressed in their reluctance to apply for posts If Dr Hendry as the head of a teaching-hospital biochemistry department can say it is all but impossible to recruit young science graduates into hospital biochemistry departments, how much more so is this the case in regard to the non-teaching hospitals administered by regional boards, and this at a time when scientists are making fundamental contributions in every branch of industry and many other fields of activity Why should the hospital service alone be denied this advantage? Surely the health of the nation should have at least an equal call on the scientific potential No medical man can view this situation with equanimity, and least of all pathologists whose own work can gain so much more significance and value by close collaboration with chemical studies It would seem worth trying to find the explanation for the unpopularity of hospital work for science graduates

Firstly, the newly graduated chemist, if he is worth his salt, will wish to advance his knowledge and status by acquiring a postgraduate qualification This requires in the case of a PH D that the department in which he works will be recognised by a university department of chemistry or biochemistry as giving proper facilities for postgraduate study together with supervision by a senior member of the staff of these departments In the case of an M SC no university supervision is required, but unless the proper facilities are there the preparation of a thesis will be impossible These facilities consist above all in adequate time—and, in the case of more senior biochemists, assistance—to pursue a research project, and there seems no doubt that the greatest drawback to the hospital biochemistry service in the eyes of would-be graduate recruits is the lack of time and encouragement to undertake research Many pathologists consider biochemical research inappropriate in hospital laboratories, especially in non-teaching hospitals, or, even if they are convinced of its value, are unable to persuade hospital management committees to provide sufficient staff to enable the biochemical graduate to devote time to original investigations He is consequently inundated with routine and repetitive work and soon becomes dispirited and leaves the service, or stays on disgruntled with a grudge against doctors in general and pathologists in particular

No greater catastrophe could befall the pathologist than to lose that intimate contact with the biochemist which promises to solve many problems which neither can solve alone Yet it is clear from Dr Hendry's letter that the pathologists' laudable attempts to weld the hospital laboratory disciplines into a single integrated team are viewed with the greatest suspicion by medically and non-medically qualified biochemists alike The reason for this lies in the question of prospects The young biochemist is not going to sit back and vegetate when he has obtained his postgraduate qualifications He hopes eventually to attain as senior and respected a position in the hierarchy of the hospital staff as he would in industry or other Government scientific establishments, and to have a reasonable chance of running his own department Under the present circumstances he will find his way blocked in both these directions He cannot obtain status comparable with his medical colleagues as long as his method of appointment is that of registrars, technicians, and radiographers—viz , by hospital management committees and not by regional boards Neither can he obtain it—human nature being what it is—as long as his salary is so much less than that of his medical colleagues that he cannot join fully with them in social activities and educate his children similarly As for running his own department, it is generally believed that the Association of Clinical Pathologists considers that the biochemist should be directly responsible to the head of the laboratory in which he works (i e , the senior clinical pathologist), though I am not aware of any published statement of this policy While not suggesting that a non-medical biochemist should be in charge of the other clinical pathological laboratories, I am at a loss to see why a senior biochemist, whether medical or non-medical, should not be in absolute charge of his department, responsible only to the employing authority Of course there will be many matters of a clinical nature which he will want to discuss with the medical pathologists, but surely discussion on terms of parity is the essence of the teamwork which we wish to see in the integrated department of clinical pathology of the future

Yet another explanation for the mistrust by biochemists of pathologists lies in the manner in which the latter are organised for political purposes The Association of Clinical Pathologists has only medically qualified full members How can it be representative of biochemists in general ? If it wishes to be considered thus representative, it must give full membership to all hospital biochemists of suitable seniority (which would seem appropriate enough if hospital biochemistry is indeed a branch of clinical pathology !) Similarly if pathological advisory committees wish to be considered qualified to advise regional boards on biochemical matters they should admit senior non-medical biochemists to membership If these suggestions are not attractive to pathologists, would it not be better for them to leave the advising on biochemical matters to the Association of Clinical Biochemists on the one hand and to regional biochemistry advisory committees, still to be formed, on the other ? While retaining their role of principal advisor to the authorities on biochemical matters, these organisations would no doubt welcome and benefit by periodic discussions through joint consultative committees with the corresponding pathological bodies

In the meantime, the recruiting position has deteriorated to a stage where it is impossible to fill biochemical appointments even with candidates who are far from ideal There is here a vicious circle The poor quality of the majority of science graduates accepting posts in the hospital biochemistry service has prevented many pathologists from gaining insight into the reliability and potentialities of the best type of biochemist Otherwise it is possible that a far greater degree of responsibility and scope would have been accorded the science graduate Now it is too late, and in despair the pathologists have turned to the young men of their own profession to fill the gap Although there is much that is attractive in the medically qualified biochemist (chemical pathologist), the disadvantages would seem far to outweigh the advantages if he is only going to have one year of fundamental study in chemistry as Professor Cappell suggests With so little experience in chemistry, how will he be able to attract to work under him keen young scientists just leaving university departments of chemistry four years after they have taken their advanced level G C E ? If he does not attract them, the standing of our departments of chemical pathology will fall below those of departments of clinical chemistry in other countries

I would suggest it would be far more long-sighted to make the hospital biochemical service attractive to the best young brains in chemistry and biochemistry by introducing the following innovations

(a) Every biochemist post advertised (or at least a considerable proportion, which should be specially designated as largely free from routine and repetitive work) should carry with it (i) facilities for obtaining a postgraduate qualification, (ii) reasonable opportunity to reach status comparable in salary and independence with that of medical consultants,

(b) Research should be considered a normal and not an exceptional activity of biochemistry departments

(c) Appointments to senior (principal and top-grade) biochemical posts should be made by regional boards

(d) Biochemistry advisory committees should be appointed by regional boards and should always include a professor of chemistry or biochemistry

Although there are many other ways in which hospital biochemistry could be made more attractive, if those mentioned here are implemented there would surely be a most gratifying influx of the best type of scientist into the service, and I should like to see pathologists taking the lead in securing these improvements because it is they who will gain most by having the privilege of working as a team in close collaboration with the finest products of our universities' scientific departments

CHROMOSOME ANALYSIS

SIR,—I was surprised by Dr Stewart's letter of Sept 17 From his statements, one may conclude that colchicine and its derivatives causes heteroploidy and triploidy in animals So far as I am aware, the few cases of heteroploidy and triploidy observed in animals were associated with a highly artificial technique

Colchicine was added to sperm material and the animals artificially inseminated In this way, a few rabbits and one pig supposed to be triploids were obtained[1] [2] However, the accounts concerning these animals have been criticised and their triploid nature is unconvincing and not yet established[3] To sum up, it is apparent from these reports that no polyploid animals have been produced by colchicine[4] Moreover, colchicine does not cause gene mutation[5]

Recently, by intrauterine injections of colchicine into female mice just before mating, Edwards obtained some heteroploid embryos at 3½ days' gestation Chromosome counts of the mature offspring of these females, however, showed no heteroploids[6] Using a different technique, similar results were obtained in rats by French workers A few "heteroploid" embryos were seen at 12th day but none at full-term gestation[7]

The method is, I believe, simple and useful The results are good, and nothing suggests that the intravenous administration of the colchicine derivative is

TREATMENT OF IDIOPATHIC HYPERCALCÆMIA OF INFANTS

SIR,—Many articles have now appeared about the treatment of idiopathic hypercalcæmia of infants A low calcium and vitamin-D intake, a high phytate intake, and the administration of cortisone have been recommended To my knowledge mention has not been made of the possible beneficial effect of total exclusion from ultraviolet rays

The antirachitic effect of sunlight is thought to be due to the activation of 7-dehydrocholesterol in skin This activation may result in the formation of substances with vitamin-D activity equivalent to 1000 or more units of vitamin D per day in infants who are exposed to ultraviolet radiation Possibly this disease has not been reported in Negroes because of the lesser effect of ultraviolet rays on deeply pigmented skin

It seems probable that infants with idiopathic hypercalcæmia are sensitive to very small amounts of vitamin D and it would seem advisable that patients with this disease be excluded from sunlight during those seasons when rays between 280 and 320 μ are present.

Possibly someone with knowledge of the metabolism of vitamin D might render judgment whether infants with idiopathic hypercalcæmia should be excluded from sunlight as part of their treatment

TREATMENT OF OBESITY BY THE HIGH-FAT DIET

SIR,—Bearing in mind case 5, and the large group of patients and friends she appears to represent, can Prof Yudkin and Miss Carey (Oct. 29) offer a 1500-calorie diet that is *permanently* acceptable both *socially* and financially to an adult woman of any age? An overweight woman is conspicuous in a crowd she does not wish to draw further attention to herself by always differing from the group when she is not eating alone

We would be most grateful

Hadleigh, Essex.

DAPHNE SASIENI

ERYTHROCYTE ENZYME DEFICIENCY IN UNEXPLAINED KERNICTERUS

SIR,—I was very interested by the contributions from Smith and Vella[1] and Doxiadis et al.[2] They confirm some observations I had the opportunity to report[3-6] last year

I have so far studied 19 jaundiced newborn children (11 males, 8 females) with unstable G S.H. and/or G -6-P D defect in their erythrocytes In 10 cases exchange transfusion was performed 7 of the transfused children and none of the untreated survived without damage Precipitating factors, such as dangerous drugs, were recognised in only a few cases Severe anæmia was rarely present, on the other hand, jaundice was often associated with severe clotting disturbances, indicating perhaps hepatic impairment, which may be due to the enzyme abnormality itself In fact, as I was able to demonstrate by liver biopsy, G -6-P D activity is decreased in the liver of sensitive individuals as well as in their erythrocytes[6] The observations of Smith and Vella and Doxiadis et al emphasise again the importance of this particular type of neonatal jaundice They also confirm the high incidence of the syndrome in a few families bearing the defect, and this fact suggests that there is a genetic factor in addition to the G -6-P D defect.

A SEVERE ANAPHYLACTOID REACTION TO HYDROCORTISONE

SIR,—Occasional allergic reactions following the local injection of hydrocortisone have been recorded,[1] and in many cases the possibility that associated use of hyaluronidase or procaine was to blame has not been firmly excluded The following case illustrates an allergic response of alarming severity to the injection of 'Hydrocortisyl' (Roussel) 5 ml in a patient who had never had either local or general steroid medication.

No other solution was injected and it was possible to exclude any previous injections (within 2 months) and any tablets or medicines (except 2 tab codein co *B P*, to which the patient was accustomed, taken a week previously) Similarly no dietary explanation could be discovered

A woman of 50 had, on April 8, 1960, a cup arthroplasty for osteoarthritis of the right hip She made a normal recovery, and was discharged to outpatients on June 17

On Sept 15, during follow-up examination, she complained of pain in the right shoulder A typical moderately severe supraspinatus tendinitis, with early pericapsulitis, was found, and at about 3.30 P M hydrocortisyl 5 ml was injected into the rotator cuff

She had no immediate ill effects, but at 7 30 P M, after supper, she suddenly felt her "face funny—blotchy with lumps, and burning" Red patches appeared on her arms, and she felt sick. She "passed out" and was carried to bed

An hour later, when her doctor arrived, she had regained consciousness, but she was vomiting profusely, had pain in the stomach and loins, and had urticaria, especially on the arms and face Conglomerate petechiæ and bruises appeared over the arms and face She was in a state of shock, with tachycardia, extrasystoles, and a weak pulse. There was much abdominal tenderness, especially in the liver area

She was given anti-histamines ('Piriton'), and she felt a bit better next day, but for 2 days she vomited repeatedly and had diarrhœa and rectal incontinence The stools were fluid and black, and the vomit contained dark blood

She was readmitted to hospital on the 3rd day Laboratory investigations showed hæmoglobin 92%, platelets 300,000 per c.mm, bleeding-time 2 min, clotting-time 6 min, clot retraction after 1 hour normal, prothrombin content 100% of normal, and prothrombin consumption normal The vomit contained dark blood, and occult blood was present in the stools The urine was normal.

Vomiting and diarrhœa ceased on the day of admission, and the abdominal pain and tenderness cleared up within 48 hours She returned home after 5 days

Although intradermal skin tests were unlikely to be helpful so soon after such a severe reaction, they were attempted on Sept. 7 using (1) control solution, (2) a minute dose of penicillin (to exclude penicillin contamination of the syringe used for injection), and (3) hydrocortisyl 0 01 ml An erythematous plaque 0 75 cm. in diameter formed in 24 hours around the site of hydrocortisyl injection, and persisted for 2 weeks, while the control sites showed no reaction

Thus it appears almost certain that this alarming reaction was due to the hydrocortisyl injection. Some

---

[1] Kendall, P H. *Ann phys Med* 1958, 4, 170

2000 hydrocortisyl injections have been given in this department over the past 3 years, and except for one case of mild infection following an injection for tennis elbow no other ill effects have been encountered from the use of these injections for the minor orthopædic troubles treated by this method

My thanks are due to Dr Josef Grutz, who dealt with this emergency so capably, and who has cooperated in the inquiry concerning ætiological possibilities

Romford, Essex

R A KING

ZOLLINGER-ELLISON SYNDROME

SIR,—With great interest I read the article in your issue of July 16 concerning this syndrome with diarrhœa and malabsorption The gastric-secretion studies before and after removal of the pancreatic islet-cell tumour were particularly striking As the Birmingham group point out, confirmation of their observation with tumours of similar type is important, so you may be interested in the story of a patient Dr G J Verdonk and I reported[1] at a colloquium of gastroenterology in Antwerp in September, 1958

A 66-year-old woman who presented herself in June, 1957, had a continuous pain in the epigastrium, spreading to the back After meals the pain was worse and she complained of heartburn and eructation She had no diarrhœa—on the contrary there was a distinct constipation She never had hypoglycæmic attacks

Examination of this fat healthy-looking woman revealed a resistance in the left upper abdomen which was at first thought to be an enlarged spleen

Erythrocyte-sedimentation rate 15 mm in one hour Hæmoglobin 12 8 g per 100 ml White cells 5400 per c mm, normal differential count Liver-function test normal No occult blood in the fæces Urine normal A fractional test-meal showed considerable hyperacidity free acid 106, total acid 120

X-ray examination of the stomach did not demonstrate an ulcer, but the mucous-membrane pattern was rough On compression of the stomach an area of lack of contrast was visible, possibly caused by pressure from behind The radiologist suggested a pancreatic tumour or cyst Just distal to the duodenal bulb a pseudopodial contour was seen, interpreted as a diverticulum

After six weeks' ulcer treatment with rest, diet, antispasmodics, sedatives, and antacids she was admitted to hospital, because the abdominal mass was still palpable We finally decided on operation On Nov 1, 1957, a pancreatic tumour, 7×6 5×6 5 cm, was removed During the operation the stomach and intestines could not be explored The surroundings of the tumour and omentum were hyperæmic and contained large dilated veins The omentum was containing the tumour and was firmly connected to the surface of the spleen The tumour was removed without vagtomy or gastrectomy The histological diagnosis was " insulinoma "

In September, 1958, nearly ten months after the operation, a fractional test-meal showed that the acid secretion was now reduced to subnormal free acid 0, total acid 16 (maximum)

The Widdicombe File

LXVII —THE DIVISION OF PATHOLOGISTS

DEAR PETER,

I too thought your letter was sound but I think your friend G G, like several of the pathologists, is not entirely familiar with the real function of a college They ask " Can we trust the physicians ", meaning presumably the internists, the dermatologists, the pædiatricians, the neurologists, the psychiatrists, and the other *clinicians* in the college, and they talk earnestly about the need for independence But, bless our souls, why do they need to be independent? A college is basically a degree-granting body and also ideally a community of individuals with kindred interests Do we hesitate to take a university medical degree because we doubt the good intentions of the philosophers or theologists who are represented in its court, or do we demand independence so as not to have to eat at table with engineers or lawyers? Maybe the young men want independence at any price because this is the parrot cry of the mid 20th century Fortunately in the college the dermatologists seem to show no distrust of the psychiatrists, and the neurologists are not afraid of being outvoted by the general physicians else there would have to be lots of new colleges What will it benefit the pathologists of tomorrow to have their own college with its expensive library and regalia, portraits and plate? Are pathologists anxious to accept the social and other obligations of a college and to maintain an expensive establishment—for rest assured they will not for long remain content with an attic in Euston but will feel the urge to compete on the perimeter of Regents Park?

Although your arguments were sound one correspondent accused you of talking nonsense His letter reveals the lack of cohesion amongst pathologists and indeed the seed of the next potential split (" Can we consultant biochemists trust the pathologists and bacteriologists?—we must be independent at all costs ") What I mean is this, Peter, if the pathologists (and I am using this term generally to include bacteriologists, virologists, chemical pathologists, serologists, forensic pathologists, and hæmatologists—all in fact who are concerned with the laboratory investigation of the patient alive or dead) do not accept this very generous offer of negotiation by the Royal College of Physicians (some claim that it will fail because it is too generous), they may have to wait a long time before achieving the unanimity they require to embark on a new venture Many of the academic pathologists—if what I hear is true—care little whether there is a faculty of the college or a new college

Please impress on your many pathologist friends, Peter, that a faculty will require an appreciable measure of support but a new college will require overwhelming support from all species of pathologists Remind them that a faculty can always be dissolved (I trust that in the event of a faculty both the pathologists and the college will insist on having this in their agreement) but once they embark on a college they will have committed their successors to a life of independence and will have severed connection with their clinical colleagues A recent president of the college, it is said, once invited the pathologists to look forward fifty years They should do this now The rapid growth of specialism, automation, and the increasing excellence of technicians may bring the pathologist of the future much nearer to the patient than he is today and nearer to the clinicians An irrevocable move at this time would be a misfortune

Yours ever,
W W

Parliament

Queen's Speech

In the Speech from the Throne at the opening of Parliament on Nov. 1 it was announced that the Government proposed to increase war pensions, and retirement pensions, other benefits, and contributions under the National Insurance schemes.[*] They would authorise an increasing level of expenditure on the physical recreation of the young. Awards for students at universities and for those taking comparable courses at other institutions of higher education would be granted on an improved basis. They would introduce a Bill to provide better means of dealing with young offenders, to extend compulsory after-care to prisoners and so to discourage them from reverting to crime, and to improve the management of approved schools.[†]

Welsh Teaching Hospital

On Nov. 2, on the adjournment, Mr LEO ABSE sharply criticised the plans for this new teaching hospital, which he described as an "ossified hospital design accepted from a septuagenarian architect by assessors led by another septuagenarian architect ... a design for a hospital for 1950, not as it should be for a 1980 hospital." Wales wanted a forward-looking teaching hospital, it was being proffered a mausoleum.

Going on to offer detailed criticisms, he said that the contemptuous attitude to research was well illustrated by the location and space allocated to the animal house. In defiance of hospital planning, the X-ray department was so embedded within the building that expansion was well nigh impossible. A derisory amount of space was allocated for radioisotopes. A trivial 32 beds had been allocated to mental illness, and there was still no sign of a department and chair in psychiatry being created. But the most dismaying feature was the ludicrous amount of space allocated for research in relation to bed space. The design gave every appearance of there having been a battle for beds between heads of departments.

Other points which he made were: quiet rooms in the noisiest part of the building, the sluice room farthest from the beds most needing its services and unrelated to treatment suite, cross-infection risks increased by infected material being brought into the ward suite for disposal and by inadequate air-conditioning, lavatories concentrated in blocks and not related to bed areas or day spaces, an operating-theatre with a wood-block floor which could never be sluiced clean, eight-storey light wells which meant that wards would be badly lit and have a wretched outlook.

All these blunders and many more, he added, would be housed in a dull cliff-like bulk of buildings unmistakably institutional in appearance.

Miss EDITH PITT, the parliamentary secretary to the Ministry of Health, welcomed the opportunity of discussing the University Hospital of Wales and of replying to some of the criticisms. The fact that it was an undergraduate medical school dictated not only the concept of the work to be performed there but also the site of the hospital, which was to have 650 beds. The scheme must be viewed against the development of acute hospital services in South Wales, which included not only another major acute regional hospital working in the Cardiff area but also major acute hospitals at Bridgend, Pontypridd, and Newport, and others in the Welsh Hospital Board's plans for Merthyr and North Monmouthshire.

The Board of Governors of the United Cardiff Hospitals and the Welsh National School of Medicine desired a hospital integrated with a medical school, with the closest possible working arrangements between the professional and the clinical staff and with the various departments and their research and other laboratories. An architectural competition for an important scheme of this size was thought preferable to selecting an architect, because it was believed that competition would give incentive to a number of architects to think about the problems set by the promoters and that new ideas and techniques might be evolved. Competition, however, could do no more than select an architect and, in a scheme of this size, a fundamental design. The promoters and architect could deal with each other on paper only in broad outline. The details must wait till later. A series of working parties had now been set up to go into the plans of the various units with the architect and with the engineer.

Ward units, outpatient department, lifts and communications, catering and food distribution, training accommodation, the dental school, were all being looked at in this way. The internal design and layout of the ward unit, for instance, had already been replanned to provide better access and better supervision; to take account of the latest thoughts on cross-infection, more single rooms had been provided, and the large ten-bed unit had been broken up into smaller units.

This was a normal process which one would expect to take place with any design, and similar replanning was going on throughout the hospital. The promoters had examined the design carefully in the light of the numerous criticisms and were satisfied that the completion of the process of preparation of detailed sketch plans, which was now going on, would give them a modern and efficient hospital and a medical teaching centre. She thought it premature at this stage to be too critical of the detailed planning because the details had still to be filled in. It was her earnest hope that, when this hospital was completed, the Welsh people would have a hospital in accordance with their wishes and a hospital of which they might be proud.

QUESTION TIME

Poliomyelitis Vaccination

At Sept. 30, 13,333,000 people in England and Wales had been vaccinated against poliomyelitis under the National Health Service.

Obituary

JAMES ERIC PATERSON

M B Glasg , F R F P S

Mr J E Paterson, honorary consultant in neurosurgery to the Scottish Western Regional Hospital Board, died at his home in Rothesay on Oct 26

He was the son of a doctor and graduated from Glasgow University in 1911 as the most distinguished student of his year He spent some years in resident hospital posts, in general practice, and in junior staff appointments in surgery, gynæcology, and anæsthetics before he joined the R A M C to serve in France during the first world war After the war he returned to general practice and part-time specialism, and in 1920 was elected F R F P S

In 1926 he was offered the post of visiting surgeon to Stobhill Hospital, Glasgow, at that time a poor-law institution with 2000 beds for the aged and the chronic sick This appointment required him to give up general practice but gave him no chance to build up a consulting practice, and its acceptance meant a considerable financial loss A colleague relates

" To be poorly paid for tending the ' dregs of humanity ' was no deterrent to this extraordinary little man From the apparent dross he extracted much gold and gained a breadth of experience which few have achieved To suit his poor-risk patients he developed multi-stage operations He quickly learned the need for meticulous preoperative preparation and postoperative care and set up a specialised anæsthetic service In the early '30s his was a lone voice preaching the gospel of biochemistry, and he used the, then, slight resources of that science to the full Blood-transfusions were commonplace in his work when they were seldom thought of elsewhere, and before the late war there was a blood-bank in Stobhill

" He was indeed a general surgeon, whose work ranged from the newborn to the geriatric patient and embraced all specialties His technique was superb Watching him operate was like turning the pages of a beautifully illustrated atlas of operative surgery The neat, the precise, the anatomical attracted him, and he derived much pleasure from his practice of abdominal and reconstructive surgery and from urology, but neurosurgery became his true love This specialty he developed step by step from zero, beginning with attempts to relieve the hopeless cases admitted to Stobhill for terminal care In less than ten years he changed his wards from what was derisively called the ' deid hoose ' to a teaching unit "

The worth of Paterson's work in neurosurgery was soon recognised, and he was appointed neurosurgeon to the Victoria Infirmary He continued to work there until the establishment of the neurosurgical unit at Killearn in 1940 When the National Health Service was started, he gave up general surgery—not without much heart-searching—and confined himself to neurosurgery

E A T , once one of his students, writes

" Two things were noteworthy about Eric Paterson The first was that he was a great man With the cultivation of a new specialty he combined modesty, enthusiasm, unmitigated frankness about himself even more than about others, unvarying truthfulness, and an uncanny habit of being right in his judgments These are not the qualities which produce an overblown reputation during a man's lifetime, but they indicate the second noteworthy feature about him, which was that his greatness was not as widely known as might have been expected Instead he built a solid foundation of friendship, respect, and those ultimates in admiration—emulation and imitation He threw away opportunities to be grandiose, he gave limelight to juniors, and he demanded no ceremony Such attributes are looked back on after years with love Even his faults were venial, for though his irascibility towards foolishness was legendary he was never hurtful His influence will outlast more brittle reputations Nor for generations will the personal magnetism of the man fade from the minds of his pupils, and his pupils' pupils for even longer the traditions of the units they serve must reflect the imprint of his character "

S A sends a physician's tribute

" Wee Pat was really known and understood by only the surgeons This was entirely proper He belonged to them Maybe physicians—second to none in their admiration for him —like to imagine this frail little man cast in a different role To them it seemed strange that a surgeon should flit through the world on tiptoe—eager, tireless, and radiant His face—specs and all—was a classic for the students sensitive to the physiognomy of intellect Few men revealed in their demeanour, voice, and gesture so vivid a spectrum of human emotions the tranquillity of deep meditation, the turbulence of the exploring mind, the flash of anger, and the smoulder of despair But most memorable of all was his dazzling smile—impish and mischievous—transforming the senior surgeon into a jubilant schoolboy, but eloquent too of his deep humanity James Eric was splendidly endowed with the attributes shared by the artist and the philosopher-surgeon he was in love with the world of beauty; and its glory and splendour were reflected in his imagination Out of these his riches he gave abundantly to patient and colleague alike they rejoice in his talents, they grew and were fortified by his example "

W G also writes of the man as well as of the surgeon

" Wee Pat's knowledge of surgical literature was immense, but surgery by no means filled his life He regarded the world with childlike wonder so that all things were of interest to him In literature, poetry, biography, music, and philosophy he was astonishingly well informed Botany and geology were his delight Sailing was a pleasure with him till it became too strenuous for his years, and then he turned to painting Critical as he was of his own efforts here, he developed his not inconsiderable talents to the full by his customary intense application Because of all his interests he was self-contained, and boredom was unknown to him, but he loved to meet a fellow enthusiast and made many friends through his hobbies

" In his earlier years his sensitivity and his enthusiasm made him a little prickly and intolerant, but the passage of time wore away the sharp edges and left a benign, mature personality as stimulating as ever He had no ambition to order other people's lives, and as a committee man he was a self-confessed failure He could not tolerate scheming and lobbying

" When he retired many groups of friends and associates gave him dinners and presentations The Wee Man was deeply touched and quite bewildered by these tokens His modesty had never allowed him to guess his own greatness nor to realise that he had gained ' that which should accompany old age, as honour, love, obedience, troops of friends ' "

Mr Paterson leaves a widow and two sons, one of whom is in general practice at Forres

Mr C W KIMBELL

G C S writes

" It was in the unpleasant circumstances of the 1940 campaign and then in captivity that Kim's sterling quality of character showed itself in all its brilliant clarity His devoted care of the wounded prisoners and his unswerving loyalty to those who served with him were an inspiration to all Small wonder that he had a host of friends who remember with affection and admiration his generosity and kindliness and his inimitable conspiratorial chuckle To all those the world is now a colder place "

Notes and News

WORLD HEALTH ORGANISATION

AT a meeting in Geneva of the W H O Executive Board, which opened on Oct 25,[1] Dr V Butrov (U S S R) stated that the U S S R would give 2 million roubles in 1961, in addition to its previous contribution, to the malaria eradication special account The Board decided to recommend to the next World Health Assembly that part of the cost of the malaria eradication programme should be financed from the regular budget The Board recommended a supplementary budget for 1961 of $800,000 This includes $100,000 for W H O assistance to the Congo, a further $2,700,000 for the same purpose will be provided by the United Nations

The Board commended Dr M G Candau, the Director General of W H O, for the promptness and efficiency of W H O assistance, and requested that it should continue They also thanked the International Committee of the Red Cross, the League of Red Cross Societies, and Governments which had helped with the emergency health programme

MENTAL ILLNESS IN SCOTLAND

AT the end of 1959[2] the total number of people in Scotland who were under care for mental illness was 20,682 (467 fewer than at the end of 1958) Of those in mental hospitals (including the State Mental Hospital at Carstairs) 14,022 were certified patients (922 fewer than at the end of 1958) and 6385 were voluntary patients (472 more than at the end of 1958) The number of admissions (excluding transfers) during 1959 was 12,428 (990 more than in 1958) Admissions of voluntary patients increased by 1175 to 9977 (80% of the total), but admissions of certified patients dropped by 188 to 2451 8719 voluntary patients (1095 more than in 1958) left hospital during the year Discharges of certified patients (including discharges " by escape ") numbered 1935 (118 more than in 1958) of whom about two-thirds were classified as ' recovered "

At the end of 1959, the total number of certified mental defectives was 8421 (98 more than at the end of 1958) Of these 5107 were in institutions and 2466 under guardianship Admissions of certified defectives to institutions during 1959 numbered 445 (53 more than in 1958) 234 patients were also admitted on an informal basis and 29 patients were transferred from certified to informal status The number placed under guardianship was 111 (8 fewer than in 1958) 215 were discharged from compulsory detention (including those discharged " by escape ")

A special study of readmissions during 1959 showed that of all admissions during the year 4480 (36%) were of patients with a previous admission 1139 were readmitted within three months of last discharge, 886 (7%) within six months, 624 within nine months, and 365 within a year

A NOVEL CLINICAL TRIAL

THE ethics of clinical trials can raise heated discussions wherever doctors meet, whether in lecture hall, laboratory, operating-theatre, hospital common-room, or students' hostel Now, perhaps because his pseudonym covers a man with an F R C S, Mr John Rowan Wilson has made a medical version of the dilemma of means and ends the centre of his novel, *Double Blind*[3]

A young bacteriologist is carrying out on a tropical island a double-blind trial with a vaccine against a form of encephalitis The trial is being financed by a German drug firm which hopes to patent part of the manufacturing process The island is an isolated primitive community under the tutelage of the Colonial Office In obtaining permission to carry out the trial in its hospitals and clinics official channels have been by-passed Though the natives normally give their permission before receiving the vaccine, it is unlikely that they realise the significance of the request On the other hand, " South Atlantic " encephalitis is an endemic and dangerous infection and its control would be an enormous benefit to the community Two deaths occur which may or may not be due to the vaccine A Catholic priest complains The Colonial Office, uneasily aware of lapses in protocol, if not in morality, send out a doctor to report on the trial

This complex epidemiological situation contains many of the important issues which beset the conscience of the research worker It is further complicated by the tense personal relations of the doctor, the bacteriologist, and his wife Their personal problems are solved by the novelist's manipulation of the plot The questions of general principle inevitably remain unsolved, but it is to their intelligent presentation that the book owes much of its unusual interest

BIOLOGICAL ENGINEERING SOCIETY

THE first scientific meeting of this society was held on Oct 15 at the National Institute for Medical Research, Mill Hill In his opening address, Sir Charles Harington drew a parallel between the state of biological engineering today and biochemistry half a century ago Perhaps in the years to come, he said, a fusion of the two disciplines of biology and engineering might result in biological engineering becoming as acceptable as biochemistry today In the meantime, advances in biological and medical science depended greatly on advances in engineering and instrumentation, and the society was making a valuable contribution by enabling biologists and engineers to work more closely together Prof R F Woolmer, the president of the society, thought it appropriate that this first meeting should be held at the Institute, for its work and organisation was a good example of the way in which engineers could work together with biologists About 100 people attended the meeting, and the programme of demonstrations was planned to give a cross-section of the subjects which the society hopes to cover

SPASTIC SCHOOL-LEAVERS

ONE of the most useful qualities of voluntary organisations is their refusal to leave fairly well alone The British Council for the Welfare of Spastics, now that they are satisfied that there is no longer a general shortage of school places for spastics, have turned their attention to the difficulties which these young people face when they go out into the world[1] A pilot survey made by the council gives a depressing picture

> Of 34 recent school-leavers only 9 were thought to be capable of becoming fully self-supporting Though 7 of these were in work only 3 were in jobs with reasonable prospects None had received any training Another group of 16 were described as ' doubtfully employable , and of these 5 were in jobs and 5 awaiting training None are ever likely to become financially independent The remaining 9 were expected to be unemployable

Thus, in all, only 12 were employed and not in very satisfactory jobs The highest wage earned was £5 10*s*, and even those of average intelligence were doing work well below their capabilities Of the 22 who are not in jobs some are in institutions or awaiting admission Others live at home and some attend occupation centres Some are waiting for training All are thoroughly under-occupied and lack enough interests to fill their days, and this leads to mental and physical deterioration In or out of jobs, they seem to lack friends and social life Clubs for the handicapped do not attract them, for whether practicable or not, they want to go out to work like other youngsters They seem to lack realism about their capabilities and of standards in the outside world, perhaps because of the inevitably sheltered atmosphere of the schools in which they were educated

The numbers in the survey are small, and the Council offer the results not as a basis for recommendations but as evidence of need. The results are a salutary reminder that, like the rest of us, the handicapped are living longer and that the support we give them must be continuous and flexible, keeping pace with their changing ages and circumstances

University of Cambridge

On Oct 29 the following degrees were conferred

M D—P A J Ball J H Cule, P C Gautier Smith, J C Kelsey, C G Rob (by proxy), David Wise
M B—T J Willis

University of Birmingham

Dr R L Edwards has been appointed senior lecturer and first assistant in the department of obstetrics and gynæcology

University of Glasgow

On Nov 5 the degree of M D was conferred on William Cullen (with commendation) and on Joseph Sluglett

University of Queensland

Dr T J Rendle-Short, lecturer in child health in the University of Sheffield, has been appointed to the newly established chair of child health in this university

Royal College of Physicians of London

Dr K D Keele will give the FitzPatrick lectures on Tuesday, Nov 29, and Thursday, Dec 1, at 5 P M, at the college, Pall Mall East, S W 1 His subject will be Evolution of Clinical Methods in Medicine

Royal College of Physicians of Edinburgh

A meeting of college was held on Nov 1, with Dr A Rae Gilchrist, the president, in the chair

A Hill Pattison-Struthers bursary for 1960 has been awarded to Dr Philip Lanzkowsky and the Jean Hunter prize for 1960 to Dr A W E Soysa

The following were elected to the fellowship

Eric James M M Whittet, Keshavarao Krishnarao Datey, H G H Richards, H R L Fraser, A B Hegarty, J S Robson, J A Loraine, Tadepalli Shamsunder Row, R C Jackson, Velva Schrire Agnes L Scott, B C Sinclair-Smith, A C Kennedy, John Butler, K L Stuart, Arthur Jarrett A R Somner D S Nand, S L A Manuwa, J H Hutchison, D F Cappell, J H Walters, K W Donald, A W Woodruff, Eric Samuel

The following were elected to the membership

C W Kidd, A P Meiklejohn, R M Vanreenen, Krishna Rao Purohit, H L Davis R W McConnachie, Thambippillai Vamadevan, A R Adams, N R Young William McQuaker Sean O Reilly, L H Harris D G B Powell, David Jacobson, Elaine M Belton, Ralph Emery, J K Binns, Sheikh Muhammad Haneef, Ram Singh, G C Timbury, Joseph Gatt Barry Lewis, Anand Mohan Sur, R G B Williamson, Hamdy Mahmoud El-Sayed, Samir Mohamed Omar Hilal, Mookencherry Cherian Mathews, A I Rae Frank Tsu Chang Hu David Burrows, Nedumchalil Markose Mathai Baboobhai Rambhai Patel B S David Achyut Govind Motiwale, Peter Taylor, N P Burns, Kishin Hingorani, J D Woolridge, Boon-Kheng Khoo, I R Lawson Pandramajal Narayanappa Krishnamurthy Khalid Haji Aboo Mitha Nalkundad Kyathappanavara Channappa, R A Osborn, Dona Priyalatha Wijesinghe, M D Bowie, Lotfy Labib Basta, Vishnukumar Gupta Erasmus Lynghdoh, M G Dunnigan, Iain Michie, Harischandra Ranasinghe, Ekpo Edet Eyo, Chenniah Javarayya Bhakta Ram, Krishnadhan Datta, Susil Chandra Munsi Subrata Sen, Cheruvcetil Kochukutty Gopi Mohammad Ata, J A Waddell, Bhim Sen Ghisaram Singhal, Chandidas Gupta, Joseph Levin, E S Garnett, Gulamabbas Juma Ebrahim, W H S George, J A McBride

Heberden Society

Dr J J Bunim will give a Heberden oration on Friday, Dec 2, at 4 15 P M, at the Wellcome Foundation, Euston Road, London, N W 1 His subject will be a Broadened Spectrum of Sjögren's Syndrome and its Pathogenetic Implications

North West Metropolitan Regional Hospital Board

Lord Moynihan has been appointed chairman of this board

Albert Lasker Grants

The American Public Health Association have awarded grants to Dr F H C Crick, of Cambridge, and Dr M H F Wilkins, of London, for their work on processes governing heredity in living cells and viruses, and to Prof Lionel Penrose for his contribution to the development of human genetics and his findings on the effect of nuclear and other radiation on human beings and their offspring

---

On Wednesday, Nov 16, at 5 15 P M, at the Royal Free Hospital, Gray s Inn Road, London, W C 1, Sir William Morrow, physician to the Royal Prince Alfred Hospital, Sydney, will speak on ulcerative colitis

Applications are invited for grants for research into diabetes mellitus and associated diseases Further particulars may be had from the secretary of the research grants committee of the Association, 152, Harley Street, London, W 1

DISEASES OF THE BASAL GANGLIA

THEIR RELATION TO DISORDERS OF MOVEMENT*

D. Denny-Brown
O.B.E., M.D. N.Z., D.Phil. Oxon., LL.D. (hon.), F.R.C.P.
PUTNAM PROFESSOR OF NEUROLOGY,
HARVARD MEDICAL SCHOOL, BOSTON, MASS.

I

The term basal ganglia has no precise limitation, having been used by the older anatomists for the large grey masses at the base of the brain, including the optic thalamus. In the present century the thalamus has been excluded, and the use of term limited to the caudate nucleus, the putamen, and the globus pallidus. For neuropathological reasons certain closely related subthalamic nuclei are often included. I shall not here discuss the intricate, and in part disputed, interconnection between these structures. The most important of these are shown diagrammatically in fig. 1, which is designed to emphasise the reflex pathway from the intralaminar (I L) and centrum medianum (C M) nuclei of the thalamus to the globus pallidus, putamen, and caudate nucleus, and the efferent connections of these nuclei with the subthalamic nucleus (S), the reticular formation of the midbrain (M B R), and the substantia nigra (S N). Short pathways connect these scattered subthalamic structures with the important motor reticular formation of the brainstem. The caudate nucleus, putamen, and globus pallidus also receive pathways from various areas of cerebral cortex. The caudate nucleus contributes an important pathway to the lateral thalamus. Though the basal ganglia are closely interrelated with the cerebral cortex in this way, they preserve both structure and function in its absence. This independent reflex activity is responsible for much of the behaviour that distinguishes the decorticate from the decerebrate animal.

My first objective is to define the degree to which diseases affecting the different ganglia produce consistent physical signs. Before 1895 there was no hint that damage to this region of the brain had any specific effect, though in the time of Hughlings Jackson it was customary to regard the basal ganglia as the seat of regulation of those simple spasms that remain when the cerebral cortex is destroyed. The first hint that specific disorders of movement are related to limited disease of these ganglia appears to have been the excellent description of congenital double athetosis by Anton in 1896, with the related scarring of the outer putamen on both sides. The most convincing demonstration, however, was the description of progressive lenticular degeneration by Kinnier Wilson (1912), providing a dramatic demonstration of the relation of limited lesions of these ganglia to rigidity, distorted posture, and tremor. Only then did the earlier descriptions of outfall of nerve-cells in the globus pallidus in paralysis agitans by Jelgersma (1908), and the comparable atrophy of the caudate nucleus in Huntington's chorea described by Alzheimer (1911), assume real significance.

As had so often happened in relation to clinicophysiological correlation in cerebral disorders, the rush to stake out claims on the anatomical terra nova outran both the available physiological philosophy and the necessary neuropathological experience. Indeed the Croonian lectures of Kinnier Wilson (1925) are wholly devoted to a sobering criticism of the massive superstructure that had already burdened the topic. The difficulties that pervade the subject are derived from the very general nature of the pathological processes that affect these structures, the kaleidoscopic variations in resulting symptomatology, and the poorly understood part that the ganglia play in normal cerebral function.

Hepatolenticular Degeneration

The striking demonstration of lenticular cavitation in hepatolenticular degeneration (Wilson's disease), though important in other respects, was most misleading in its implication that the disease process was itself localised. The widespread nature of the gliosis that accompanies all forms of the disease (Hall 1921) is now generally recognised. That the disease is an inborn error of metabolism resulting in accumulations of protein-bound copper in many organs, particularly the liver and nervous system, is also well understood. Within the nervous system greatly increased concentrations of copper are present in the putamen and thalamus, and to a less extent in the cerebellum and cerebral cortex (Cumings 1948, Spillane et al. 1952, Cartwright et al. 1954). The striking improvement that can follow removal of small amounts of copper from the body by chelation indicates that, in some cases, a

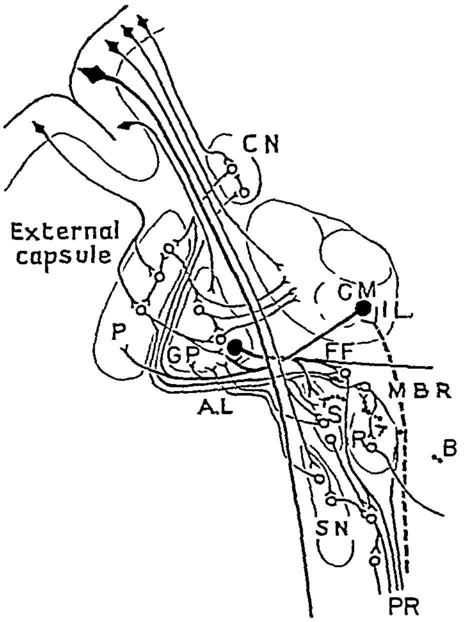

Fig. 1—Diagram of the chief connections of the basal ganglia.

The efferent systems of the globus pallidus (G P), putamen (P), and caudate nucleus (C.N) pass through the ansa lenticularis (A L) to the fields of Forel (F F). There they reach the subthalamic nucleus (S), the scattered nuclei of the midbrain reticulum (M B R.), substantia nigra (S N), and red nucleus (R.), with connections to the reticular nuclei of the pons (P R.). The reflex circuit has an afferent limb in the lemniscus and ascending tegmental tracts (represented as a broken line) through the intralaminar (I L) and central (C.M) nuclei of the thalamus. The midbrain and subthalamic reticular nuclei receive terminations of the brachium conjunctivum (dotted line B C.).

---

* From the Croonian lectures for 1960, delivered before the Royal College of Physicians of London on Feb. 23 and 25.

relatively small fraction may in time interfere with vital enzyme function In the juvenile type such improvement is unfortunately offset by other unknown factors

When the symptoms start after the age of 20 the disorder appears as flapping tremors at the wrist and shoulders, which are absent at rest and provoked by movement The very diffuse gliosis of the nervous system that is then present makes it impossible to relate such incoordination to damage to any particular structure The tremor has some features in common with that caused by other types of damage to the midbrain reticulum The fate of such cases is usually determined by the severity of the associated hepatic cirrhosis If they survive for long a generalised mild muscular rigidity ultimately appears in all limbs, predominantly in flexion, in association with severe dysarthria and dementia There is then widespread fibrosis of the cortex, thalamus, and basal ganglia

In the juvenile types of Wilson's disease involuntary movements of a different kind occur These are at first small involuntary lapses in posture At or about the same time the natural facial expression changes, the mouth is *held more constantly open, and the eyelids blink seldom* The changes in expression, associated with slight postural changes in the hands in the nature of overextension of the fingers (fig *2a*), long precede the dysarthria and facile smile that were noted by Wilson Gradually the postures of the limbs become more stiff—at first in walking, when they tend to overextension first on one side and then on the other—leading to an awkward clumsy gait A plastic rigidity is then apparent in the affected limbs It is at this time that a slurred dysarthria is usually first noticed As the disorder progresses first one then the other arm becomes flexed in a hemiplegic posture, and the lower limbs become more constantly extended As these postures develop, tremor usually appears In some patients the tremor is that of the adult type of the disease, a rapid alternating flapping at the wrist and fingers In others it begins as athetosis, with slow swings from overextension of the hand to overflexion In this type the swing of movement may in time accelerate and make gradual transition into a parkinsonian type of tremor In most patients the swings of athetoid movement become slowed by increasing rigidity, the hand becomes more continually flexed and the ankles overextended as part of the terminal hemiplegic dystonia that was illustrated so well in Wilson's original description

I should like to draw particular attention to the evolution of the terminal dystonic state in hemiplegic attitude, for this has, in my experience, been invariably present when bilateral rarefaction or frank cavitation of the putamen has occurred In time there is yet a further change in the symptomatology, in the nature of lessening of the hemiplegic rigidity, and its conversion into a state of mild general flexion (fig *2b*), with flexed wrists and extended fingers and ankles If the patient is lifted from the bed, the limbs still stiffen, resuming in some degree the earlier rigid hemiplegic posture (fig *2c*) I shall later return to the significance of these postures, for they are a key to much that is obscure in the pathophysiology of the basal ganglia

Huntington's Chorea

It is not necessary here to outline the characteristics of Huntington's chorea except to point out some distinctive

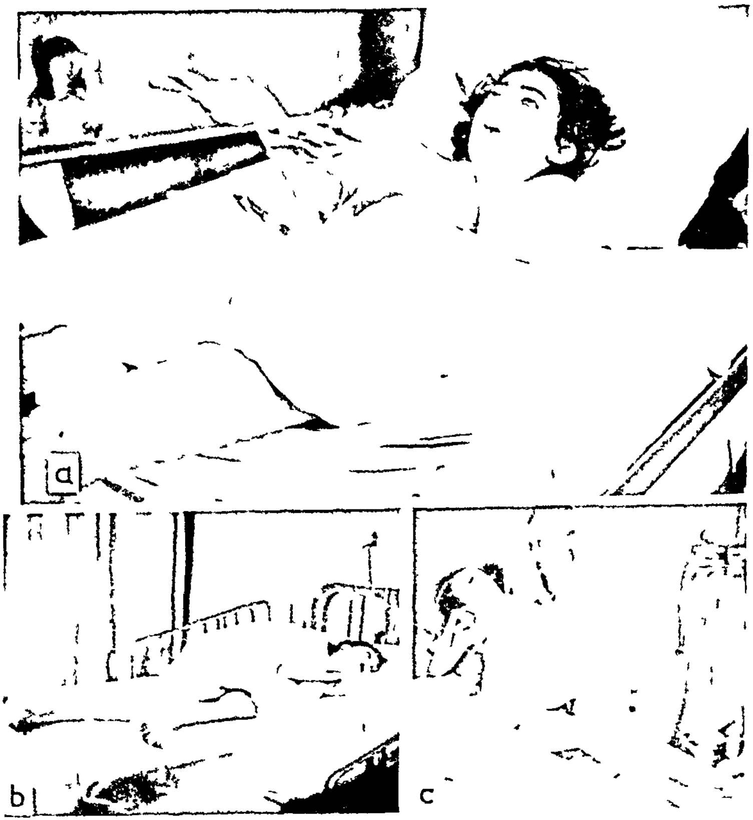

Fig 2—To show (*a*) the early abnormalities of posture in a patient of 16 beginning to show signs of hepatolenticular degeneration *In (b) is shown the posture of the* same patient 4 years later in an advanced stage of the disease (note the overflexed wrists with extended fingers) If the patient is lifted from contact with the surface of the bed (*c*) all limbs stiffen and the lower limbs extend

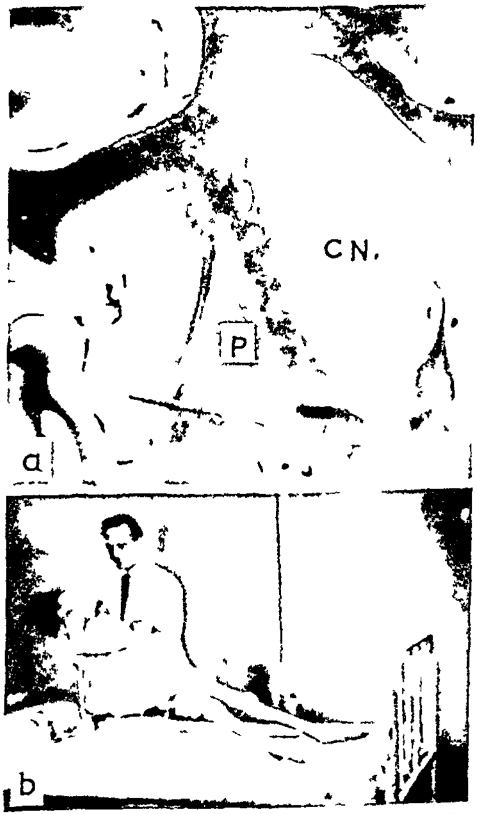

Fig 3—To show (*a*) the extreme atrophy of the caudate nucleus (C N) and to a less degree of the middle third of the putamen (P) in an advanced stage of Huntington's chorea; and (*b*) the rigid posture when such a choreic patient is raised from the bed

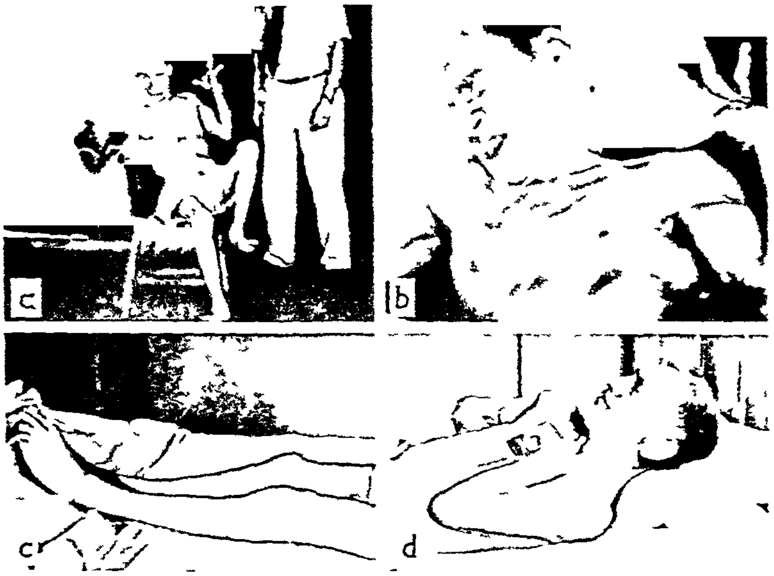

Fig 4—To show the "mobile spasm" with athetosis of hands and lips (*a* and *b*) in double athetosis. In the terminal stage a rigid posture of extension of the lower limbs (*c*) and flexion of the upper limbs (*d*) replaces the "mobile spasm"

features of the involuntary movements and postures The movements are essentially labile and haphazard in distribution. I have described elsewhere (Denny-Brown 1950) how the movements of the hands and arms gradually assume the swings of posture seen in athetosis, though at a faster rate. This is first seen in walking The movements of the lips and jaw gradually develop the wider amplitude, with associated incoordinate action of the platysma muscles, that is a feature of double athetosis For a long time the limbs are hypotonic, but the posture gradually becomes more stooped, and in late stages of the disease rigidity may appear, with more characteristic slower athetoid movements The posture is then a rigid hemiplegic attitude, which is greatly intensified by raising the patient from contact with any surface (fig 3) The arms are strongly flexed, and the legs and ankles stiffly extended. This posture is the same as that mentioned as a late stage of Wilson's disease

When the onset is early, rigidity may be the most prominent symptom (Kehrer 1928) There is then close resemblance to parkinsonism, including pill-rolling tremor of the fingers (Fleischhacker 1924, Josephy 1936) In a few patients unmistakable parkinsonism develops later in life (Chandler et al. 1960) though the lower limbs are, in my experience, more often extended stiffly than flexed in the usual parkinsonian posture. Besides atrophy of the frontal cortex shrinkage of the caudate nuclei is almost universally present, together with some loss of cells in the middle third of the putamen (Marie and Lhermitte 1914, Dunlap 1927) with pallor of the corticostriate and striopallidal systems (fig 3) A condition of fibrous scarring of the putamen, called "status fibrosus" by the Vogts (1920) and Jakob (1923), has been found in the cases presenting rigidity (Bielschowsky 1919, Terplan 1924 Freund 1925) In some cases the degeneration extends to the globus pallidus and subthalamic nuclei The extrapyramidal manifestations of Huntington's chorea, as with Wilson's disease, are seen to form a spectrum of types of movement disorder in relation to an evolving pathology, ranging from early myoclonic twitchings in some cases to torsion spasm and rigidity and, more rarely, parkinsonism The most characteristic choreic movements reflect only the usual early affection of caudate nucleus and frontal cortex.

Double Athetosis

The case selected by Vogt (1911) as the prototype of striatal disease presented an unusually well-localised marbled scar in the outer segment of the putamen on both sides The clinical symptoms are usually a bilateral labile type of athetosis affecting all parts, but particularly the hands, mouth, and neck, and present from the first year of life The condition is now well recognised, and is usually called "double athetosis" (fig 4*a* and *b*) The scar tissue appears to be a static inactive process Many follow Courville (1953) in attributing it to anoxia at birth. In several cases there has been similar scarring of the cerebral cortex (Alexander 1942), but there is no doubt that the lesion in the putamen can occur alone, and in association with a bilateral mobile type of athetosis present from soon after birth. In many cases rigidity of the limbs appears later, gradually slowing the athetosis to "mobile spasm" and leading ultimately to intense flexion of the upper limbs and extension of the lower limbs (fig 4*c* and *d*) When rigidity has complicated athetosis in this way the scarring of the putamen is usually more extensive, but few cases have been analysed from this point of view

Dystonia Musculorum Deformans

In its progressive form, dystonia is the most striking and grotesque of all neurological disorders The progressive small spasms of flexion of a lower limb, or alternatively of torticollis, that are usually the first manifestations in early childhood, first appear as additions to movements such as walking Only when continuous maintenance of the abnormal posture occurs is the dystonic condition recognised. Though I have earlier indicated the essentially athetoid character of the beginning of the disorder (Denny-Brown 1945), its relation to athetosis is still overlooked, for the first signs are spasms in willed movement rather than involuntary movements. As the disorder progresses new intermittent elements of athetoid spasm make their appearance, they are set up, like the first, by any stimulation or attempted movement. but they gradually become more constant. The cumulative steady spasm of flexion of proximal joints has added to it extension of the fingers and toes, retraction of the jaw and lordosis The later addition of intermittent spasm in antagonistic muscles followed by continued contraction in antagonists, leads to the great deformity Unless there is accompanying spasticity, the asymmetrical postures and movements can be profoundly changed by altering the areas of body in contact with the bed or examining table. If the patient is lifted free from all contact with the body surface, save for support under the axilla, the upper limbs flex and the lower limbs extend in hemiplegic posture (fig 5) If movements have been in progress they cease when the child is suspended When the patient lies on one side the lowermost limbs extend and the uppermost flex These changes indicate that reflex effects from contact between the body and supporting surface are important factors in the production of the abnormal movements and postures

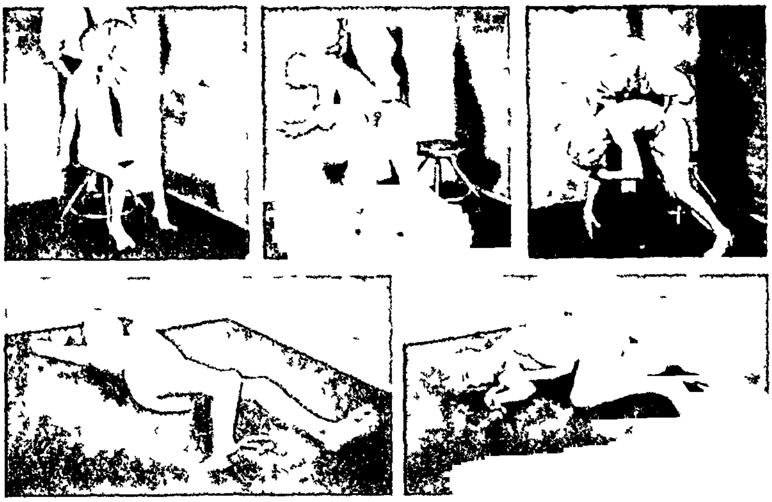

Fig 5—Dystonia musculorum deformans To show the abnormal attitudes and their modification by suspending the patient and by lying on a flat surface
(Photographed at Wrentham State School, with kind permission of Dr Carl Quinn)

Dystonia is a symptom complex that has many causes, but the irregular and grotesque progressive deformity described above, with cumulative development in one body part after another, has not been clearly correlated with pathological processes other than status marmoratus, which closely resembles the lesion of double athetosis, but usually involves the thalamus and cerebral cortex in addition to the putamen Thomalla (1918), Wimmer (1921), Jakob (1932), and others have reported the lesions of Wilson's disease in relation to relatively symmetrical dystonia Lethargic encephalitis was undoubtedly the cause of many cases of asymmetrical dystonia of partial and arrested types The cases of Cassirer (1929), Jakob (1923), Marinesco and Nicolesco (1929) and Laruelle and van Bogaert (1929) showed milder changes in the form of pallor of the globus pallidus and cell loss in the putamen There is some possibility that such cases are postencephalitic

More Diffuse Lesions of the Basal Ganglia

From the great variety of diffuse degenerative processes that affect the basal ganglia, I have singled out Wilson's disease, Huntington's chorea, and status marmoratus as examples where rigid " dystonic " states can be related to relatively localised destruction of the putamen Before turning to the problem of parkinsonism, we should briefly review some of the other types of diffuse pathology that affect the basal ganglia These are all rare and obscure syndromes, and I shall here only comment on the type of movement disorder in relation to anatomical lesion

Calcification of the basal ganglia (Fahr's syndrome) is an affection of the walls of small blood-vessels of these organs that may reach considerable intensity, even to the degree of visibility in skull X-rays (Fahr 1930), without neurological symptoms There may or may not be associated hypoparathyroidism (Sugar 1953) The neurological disorder that eventually appears is a generalised rigidity, most commonly beginning in the lower limbs (Fritsche 1935, Chavany et al 1949), with or without athetoid movements Parkinsonism developed in middle life in the patients of Jakob (1923) and of Alexander and Tucker (1949) The calcification in such cases begins on the border between the putamen and globus pallidus In a remarkable familial case of my colleague, Dr Paul Yakovlev, such calcification resulted in dysarthria with intense ridigity of all limbs in flexion

Similar flexion postures eventually result from diffuse *lipidosis* of the juvenile type (Sjogren 1931, Watson and Denny-Brown 1953) Similarly in the *Hallervorden-Spatz syndrome*, where deposits of iron-containing pigment accumulate in the globus pallidus, thalamus, substantia nigra, and dentate nuclei, there results a diffuse rigidity of the limbs in flexion, with or without athetosis It is also notable that, both in this syndrome and in lipidosis, there is a liability to sudden jerks of the limbs in flexion (myoclonus) as a prelude to the eventual postural change

The Enigma of Parkinsonism

The most common of extrapyramidal syndromes—parkinsonism—presents the most difficult problems in this whole group of diseases There is still no agreement as to the essential change in anatomical structure

The pallor of the ansa lenticularis and related efferent pathways of the pallidum, and the progressive loss of cells in the globus pallidus and, to a less extent, the striatum, described by Jelgersma (1908) and by Lewy (1913), have been found by many others (Lhermitte and Cornil 1921b, Bielschowsky 1922, Jakob 1923, Foix and Nicolesco 1925) In 1919 Tretiakoff drew attention to some loss of cells in the substantia nigra in paralysis agitans, as well as to the severe destruction of this nucleus in postencephalitic parkinsonism This feature of the disease has gained greater emphasis in the past twenty-five years (Hassler 1937a and b, Benda and Cobb 1942) Greenfield and Bosanquet (1953) have confirmed scattered cellular changes in the locus cœruleus of the pontine tegmentum, as well as in the substantia nigra, found earlier by Foix and Nicolesco, and by Hassler In his posthumous textbook on neuropathology, Greenfield (1958) states that the lesions in the globus pallidus, though constant and sometimes severe, are " essentially those of senility "

Our own pathological material in the Boston City Hospital consists of 21 cases, 5 of them are clearly postencephalitic, 7 have atherosclerotic lacunar lesions in the putamen, and 9 could be clearly calssified clinically and pathologically as idiopathic paralysis agitans Only 2 cases had been subjected to serial whole-brain sections, but multiple sections of the basal ganglia and midbrain of all the others were available for study

All cases of parkinsonism exhibited some degree of pallor of the globus pallidus and the ansa lenticularis, in sections stained for myelin sheaths The corresponding loss of nerve-fibres was more impressive than loss of nerve-cells In *paralysis agitans* the pallor was usually uneven, and foci of loss or thinning of myelin sheaths were particularly evident in the outer pallidum near the external lamina In Nissl sections such foci were represented by small inconspicuous areas of loss of cells from the otherwise evenly scattered pattern of pallidal cells In 2 cases small concretions were present in the ground substance, not directly related to the foci Gliosis was mild in degree In no case was there any evident disease of blood-vessels, other than some mild siderosis in 2 cases (a change commonly found in the globus pallidus after middle life) In one patient who died after a head injury all striopallidal and corticopallidal fibres stained very poorly compared with the pallidal efferents in the ansa lenticularis In the most severely affected cases all the pallidal cells were shrunken and stained poorly, and their lipid content appeared to be increased in relation to their size In 5 cases, and doubtfully in 2 the substantia nigra showed the small lesions described by Hassler No cell or fibre lesion was found in the nigra in 2 cases

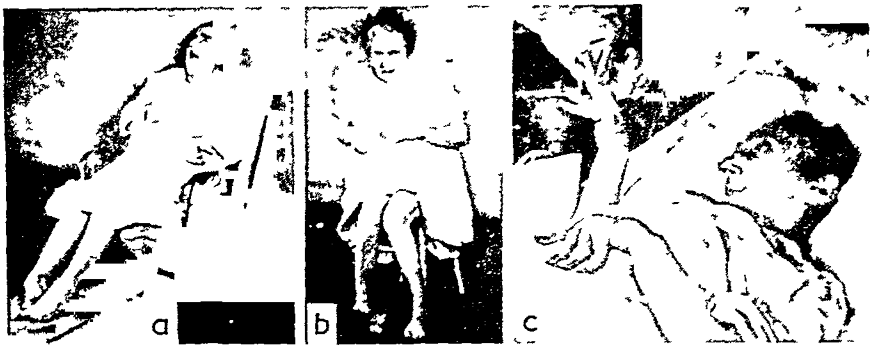

Fig 6—Terminal stages of paralysis agitans, to show flexion dystonia

The lesion of the globus pallidus is described by Bielschowsky (1922), and in detail by Foix and Nicolesco (1923, 1925), who called it "paravascular degeneration." It was regarded as the first stage of a change that later leads to more evident loss of tissue elements (*etat precrible*), and later still to pericapillary destruction of tissue (*etat criblé*). It should be emphasised, however, that in paralysis agitans with paravascular degeneration no evidence of change in the walls of blood-vessels can usually be found. If siderosis is present it must be an independent abnormality, for it can be severe in degree without producing paravascular degeneration. The pattern of tissue damage reflects some peculiarity in the permeability of the smallest blood-vessels in this area, and is common in the earliest stage of some of the metabolic diseases affecting the basal ganglia.

When *atherosclerosis* has affected the vessels of the basal ganglia, lesions of the putamen are more obvious than those of the globus pallidus. Lacunes of softening appear in the putamen surrounded by foci of *etat crible*. The clinical state is then most commonly that of pseudobulbar paralysis, with or without damage to the internal capsule and cerebral white matter. In 2 of our cases with typical parkinsonian tremor and attitude, mild *crible* lesions were limited to the internal part of the putamen and outer globus pallidus. Only associated atherosclerosis of the arterioles, and the presence of the *crible* state in the putamen, then differentiate arteriosclerotic parkinsonism of this type from what we would call true paralysis agitans. The pericapillary degeneration itself is more severe but otherwise closely resembles "paravascular degeneration." There may be small foci of similar paravascular degeneration in the substantia nigra, but these are not necessarily present. Paravascular degeneration, I believe, is not directly the result of atherosclerosis but is worsened in extent and degree by its presence. The evidence for this will presented elsewhere. The occasional cell inclusions that have been noted by Lewy (1923), Hassler (1937a), and Greenfield and Bosanquet (1953) in the substantia nigra have been found in the Boston City Hospital in all types of case. I am not convinced that they are a primary or specific change.

In my monograph in 1945 I made a sharp distinction between true paralysis agitans and arteriosclerotic parkinsonism. With greater experience I have to admit that this distinction is not absolute. There is every degree of transition. At one end of the scale one can recognise a slowly progressive gentle tremor at rest, with mild rigidity, that may begin in the fifth decade, with slight paravascular changes limited to the globus pallidus. At the other extreme the marked rigidity and fixed hemiplegic posture of the pseudobulbar type is related to the "lacunar" state, with multiple small infarcts of the putamen. Between lies every conceivable relative proportion of tremor and rigidity. Thus arteriosclerotic parkinsonism may begin with rigidity, tonic grasp, and tonic foot response, with very little tremor. In this type the putamen appears to be invariably damaged, and is perhaps first affected. Yet rigidity can also occur with pallidal lesions. A patient of mine, an 81-year-old man who had first developed typical parkinsonian rigidity and tremor twenty-one days before death, presented recent partial infarction (circumscribed pallor) of the globus pallidus on both sides. There was no change in the substantia nigra. Lhermitte and Cornil (1921a) cited a similar case.

The symptomatology of paralysis agitans consists of the well-known tremor and rigidity. In the tremor the opposed thumb beats against the first finger, and is associated with tremor of the lips and tongue before other parts. The soft yielding plastic rigidity of paralysis agitans appears first in the flexors of the upper limbs, and is associated with delay in initiation of movement, though the relative degrees of bradykinesia and objective rigidity are greatly variable. Seldom is it emphasised that in typical paralysis agitans the rigidity is invariably associated with change in posture, its preponderance in the flexor groups gradually leading to the stooped posture with flexed limbs, fixed facies with staring eyes, and open mouth, by which parkinsonism can be recognised in a photograph. It is important also to emphasise that in the natural course of the disease the postural change gradually worsens until in a terminal stage all the limbs are drawn into a fixed attitude of general flexion (fig 6). The wrists are then strongly flexed and pronated, the fingers are extended, and the ankles are plantar flexed. Attempted displacement of any part away from this attitude then meets a mounting resistance, and the part rapidly returns to its resting attitude. This terminal loss of plasticity is associated with great lessening or loss of the tremor. Speech is also lost or reduced to a mumble.

Studies of arteriosclerotic parkinsonism indicate that the coarser the lesions of the external segment of the globus pallidus the more rapid has been the development of dystonia, with correspondingly less evident tremor. If the putamen is involved tremor may not occur, and the rigidity is then not only more intense but also involves the extensors of the lower limbs and the flexors of the upper limbs (hemiplegic distribution). The pattern of rigidity as well as its intensity reflect the more lateral and lacunar lesions.

In *postencephalitic parkinsonism*, though the same tremor may be present, it is more often damped or abolished by an intense asymmetrical rigidity. The rigidity passes more rapidly into the fixed attitudes of dystonia, leading to torticollis, scoliosis, and grotesque postures of the limbs. On the side on which dystonia was absent or delayed in appearance, the tremor tends to be more violent and more extensive than in paralysis agitans. In addition various forced movements and compulsions, of which the oculogyric crises are the best known, are peculiar to the postencephalitic state. Like others, we at Boston have found a severe destruction of the substantia nigra in all cases, but we have also found a diffuse pallor of the fibre systems of the globus pallidus Obvious nerve-cell changes in the globus pallidus or striatum are seldom found, but small foci of lesser change are common More important, we have often found loss of the small thinly medullated fibres entering the external putamen from the external capsule, and the external lamina of the globus pallidus from the internal capsule, with or without paucity of striopallidal fibres There is corresponding gliosis This inconspicuous change is of great significance in relation to the prominence of symptoms of corticostriate and corticopallidal disorder, and I shall return to it in my second lecture In the acute stages of lethargic encephalitis destruction of the substantia nigra was commonly found in patients without parkinsonism (Meyer 1923, Holzer 1926) If 75% of the substantia nigra is destroyed in most cases of postencephalitic parkinsonism, this still fails to account for the varied and complex disorders of motor function of that disease, and their delay in appearance Still less is the similar symptomatology in paralysis agitans explained by the inconstant meagre changes in the substantia nigra and locus cœruleus in that disease

Focal Lesions of the Basal Ganglia

The natural history of diseases that commonly affect the basal ganglia of the brain has been outlined in order to draw attention to their general tendency to produce involuntary movements that progress slowly to states of rigid maintenance of abnormal attitude We shall now turn to the effects of acute destructive lesions, which, by contrast, produce striking disorders of attitude from their beginning

Necrosis of the Striatum (Putamen and Caudate Nuclei)

Bilateral symmetrical necrosis of the caudate nucleus and putamen has been found in conditions such as death from status epilepticus in children, when anoxic damage to small vessels is presumably the primary mechanism

Marinesco and Draganesco (1929) describe this condition after convulsions in a child aged $4^1/_2$ years, who survived to the age of 6 There was patchy laminar necrosis of the cerebral cortex, and only mild degenerative changes were found in the globus pallidus Until death the child lay in an unresponsive state without making purposeful movements There was complete absence of speech, and swallowing was difficult At first the limbs were extremely rigid in flexion, but they would extend with changes in posture, and athetoid movements were present Later rigidity was less evident when the child lay on a surface, though all the limbs were semiflexed, the wrists pronated, the fingers flexed, the ankles extended, and the toes plantar flexed When the child was suspended in air, all the limbs became intensely rigid, the arms flexed, the hands clenched, the lower limbs extended, the ankles inverted, and the toes flexed This posture would persist as long as the child was suspended This phenomenon of the appearance of rigidity when the patient is lifted from a surface is commonly called ‘ the Foerster syndrome ” Foerster (1909), however, described only the atonic type of cerebrocerebellar diplegia, and the extension of the limbs when suspended appears to have been first described by Batten and von Wyss (1915)

Hawke and Donohue (1951) described, in a 13-year-old child, a similar complete bilateral necrosis of the whole corpus striatum, caudate, putamen, and globus pallidus, which occurred during a febrile illness complicating otitis media, without any known episode of anoxia During two months of survival the child did not speak or respond to commands The eyes would follow the movements of another person, and even moving objects late in the survival period The muscles were at first hypotonic, but they gradually became stiff in flexion, particularly during passive movement Occasional myoclonic twitching of muscles was observed The remarkable phenomenon of rigidity when suspended is not mentioned by these workers Similar cases have been reported by Verhaart (1938)

Complete clinical and anatomical studies of cases of unilateral destruction of the putamen and caudate nucleus are equally rare I cannot here discuss in detail such a case in the collection of my colleague Dr Yakovlev, suffice it to say that for the last ten years, before death at the age of 25, the patient had presented a dystonic contracture of the right arm in flexion and the right leg in extension, with consistent flexor plantar responses There was a severe spastic dysarthria Mobile athetoid spasm of the hand had preceded the dystonic attitude of extended fingers, and flexed wrist and elbow Steck (1921) reported a similar case, though the dystonia was not fully described

When bilateral partial cystic infarction of the putamen has occurred without damage to the internal capsule, the clinical condition has been that of pseudobulbar palsy (as first described by Richard Bright 1831) The pseudobulbar state resulting from Wilson's disease, and the condition resulting from manganese poisoning (Peñalver 1955, Berry and Bidwai 1959), have obvious features in common

Necrosis of the Globus Pallidus

One of the most striking lesions of the basal ganglia is the symmetrical necrosis of the globus pallidus found in patients who have had an episode of coma as a result of inhalation of coal gas, or carbon monoxide, or occasionally nitrous oxide, and rarely in those who have had other types of asphyxic anoxia It can also follow intoxication by carbon disulphide (Richter 1945)

The patient commonly recovers from the initial coma, and he may be discharged from hospital apparently completely relieved, or with only slight mental confusion After one to three weeks, he may then relapse into coma a second time, and succumb in that state Most often the delayed relapse presents as the onset of an akinetic mute state, with rigidity In other cases the relapse takes the form of renewed confusion in which elements of visual agnosia and catatonic postures are prominent, presumably resulting from lesions of cerebral white matter In a few cases a mild parkinsonian rigidity makes its appearance within six weeks of recovery from the initial coma

I need not here discuss the many interesting aspects of the neuropathology, which has recently been reviewed by Meyer (1958), whose earlier papers are among the most authoritative Widespread patchy areas of cortical ischæmic damage may occur Their presence is to be suspected whenever mental confusion is persistent The lesion that concerns us here more particularly is necrosis of the globus pallidus It is commonly found when death has occurred soon after exposure, without recovery from coma, and it is usually bilateral and approximately symmetrical Some part of the globus pallidus, usually the most anterior part of the internal segment, is the site of a hæmorrhagic softening, commonly occupying only a small part (10 to 20%) of the nucleus There is usually no incrustation of the vessels in this early stage The necrosis is clearly secondary to vascular damage

Where death has occurred after a delayed relapse, with onset of akinesia and rigidity, the infarct is usually larger, and it may involve the external segment or even portions of the putamen An associated lesion of the substantia nigra has been reported (Hiller 1924) but is very rarely found In a few such cases evidence of cortical damage is very slight, and white-matter lesions have been absent

Of 2 such cases followed closely in life, 1 showed an unvarying akinetic state for six months

This 58-year-old man was found in coma in a small unven-

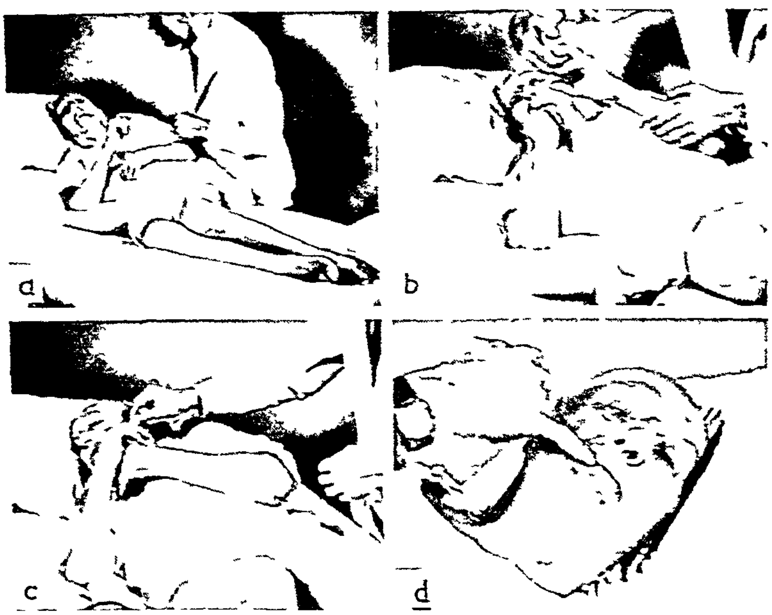

Fig 7—Carbon-monoxide poisoning: (a) to show the flexed akinetic mute state, (b) the absence of grasp response, (c) the small response to pinprick on the face, and (d) tight closure of the mouth when lips were touched.

tilated hut, with a burnt-out brazier fire, without chimney. He lay unreflexic for a day but then made a rapid recovery. Eight days later he was able to speak, to read a newspaper, and to travel from Florida to Boston. On the ninth day he was found to be very drowsy, and he rapidly lapsed into an unresponsive state, with arms and legs moderately rigid in semiflexion. His eyes were open and they occasionally followed the movements of the examiner. He slowly scratched the face if pricked with a pin, but he gave no other reaction. The deep-tendon reflexes were present but not increased. Both plantar responses were extensor. The face was expressionless. Swallowing was possible only if fluid was introduced far back into the mouth. Any attempt to open the lips or mouth passively met increasing resistance. The limbs were held continuously in a semiflexed posture, the wrists were flexed, and the ankles extended. Because of mild plastic rigidity, they resisted attempts to extend them passively. The fingers were extended and were not used, except for a feeble brushing movement at a noxious stimulus to the face. There was no grasp response to a light stimulus, but, occasionally, after heavy stroking, a feeble grasp was obtained. Such responses are illustrated in fig 7 from another patient who survived in an identical state for many months but in whom necropsy was not obtained.

In the first patient examination of the brain showed the characteristic lesions of the globus pallidus. There was no lesion of the substantia nigra, or thalamus, or other part of the extrapyramidal system. The cortex was virtually unaffected, but some patchy lesions in the frontal white matter of the orbital cortex were found on both sides, with a smaller lesion in the deep parietotemporal white matter. In this case vascular lesions of two different stages were apparent, supporting the hypothesis that the lesion had in fact enlarged after the latent interval. The occluded vessels were calcified in the area of more recent extension of softening.

In general small pallidal lesions have not been associated with extrapyramidal signs other than slowness in initiation of movement. The most intense akinesia and rigidity has followed large lesions. Where rigidity in flexion has followed after a long interval, I suspect that the lesion has enlarged because of delayed vascular changes, even after as long as seven years (Alexander 1942), and even forty-nine years in the report of Yakovlev (1944).

Focal Subthalamic Lesions

Discussion of the involuntary movements of *hemiballismus* resulting from lesions in the subthalamic nucleus will have to be omitted, except to emphasise that the characteristic movement involves a rotary element at proximal joints. This rotary element also appears in the posthemiplegic chorea associated with some types of thalamic lesion, and in the “ midbrain ” tremor so well described by Holmes (1904). When progressive lesions affect the general region of the midbrain tegmentum, rigid extension and internal rotation of all limbs eventually appears. This is the most common type of “ decerebrate rigidity ” encountered in man. Cathala (1922) has described a unilateral example resulting from tumour of the tectal region.

General Conclusions

In this necessarily abbreviated account of the general aspects of the symptomatology of diseases of the basal ganglia I have emphasised the diffuse nature of the pathology of such diseases, and their general tendency to produce involuntary movements that gradually make transition to abnormal postures. These two features are of special importance, for one of the most baffling aspects of these syndromes has been the inability of the physiologist to reproduce them by surgical or electrolytic lesions. It has not been appreciated that focal necrotic lesions of the putamen and globus pallidus can in man produce the terminal states that are seldom reached by degenerative diseases of the same structures. In particular I would stress the akinetic mute state of general flexion of all limbs, with pronated wrists and extended fingers, that is characteristic of severe destruction of the globus pallidus (“ pallidal syndrome ”). In milder degrees there is associated tremor of parkinsonian type. In contrast the more rigid flexion of upper limbs and extension of the lower limbs, greatly intensified by suspending the patient free of contact with body surface, is characteristic of destruction of the putamen and caudate nucleus (“ striatal syndrome ”). Lesser degrees of this disorder are characterised by athetosis and “ mobile spasm ”. With these two basic postural changes in mind their physiological meaning, and the significance of the disorders of movement that are associated with them, may be approached.

(The references will appear at the end of the second lecture.)

“ The more efficient society becomes at rapidly modifying our environment and our ways of life the more unpredictable are the responses of man to the new conditions of his own making. In order to meet its professional responsibilities, medicine must add to its preoccupation with disease the study of the responses of normal man to the rapidly changing environment. It must supplement the knowledge of pathology with a new science which might be called biological technology. At least, this is the conviction which has led me, a bacteriologist, to focus my thoughts increasingly on the factors, external and internal, which condition the response of man to the microbes which are an ubiquitous part of his environment.”

In a review of the possible causes of sudden death in infancy, Barrett (1954) suggested that of such cases " perhaps the majority are due to the inhalation of regurgitated food into the lungs " The inhaled food might not cause death by directly obstructing the air-passages an amount of milk too small to cause immediate asphyxia might excite an inflammatory reaction accompanied by pulmonary œdema, or the absorption of undue amounts of milk derivatives into the blood-stream might cause a state of shock

Such effects of inhaled food or vomit, if they occur, might be due either to an inherent toxicity of the inhaled material when it enters the body by this abnormal route, or to an anaphylactic type of reaction resulting from antigenic sensitisation

We present some experimental evidence which suggests that the second, but not the first, of these two mechanisms is indeed a possible cause of sudden death in infancy The hypothesis is that some infants may be in a hypersensitive state from the development of antibodies to the proteins of milk absorbed from the alimentary tract Infants often regurgitate stomach contents while asleep, and should some of this material be aspirated into the respiratory tract of an infant which has become hypersensitive, the result might be fatal

There is no doubt that most infants fed on cow's milk develop antibodies to the proteins of the milk Gunther, Aschaffenburg, Matthews, Parish, and Coombs (1960) using a sensitive technique—the coated tanned red-cell test of Boyden (1951)—showed milk antibodies in normal children aged 7–97 weeks in a titre up to 1000 with a modal distribution around a titre of 64

There thus seems to be ample evidence that the majority of infants are immunised to some degree or other to the proteins of cow's milk, and the possibility exists that these or other types of antibody may sensitise the tissues of the infants Anderson and Schloss (1923) showed that in infants with some types of nutritional disorders, milk proteins were absorbed via the alimentary tract and that subsequently precipitins to milk protein could be shown in the infants' sera, and these antibodies could sensitise guineapigs passively to anaphylaxis According to Clein (1958), up to 6% of infants during the first few months of their lives are allergic to cow's milk

Parish, Barrett, and Coombs (1960) showed that administration of milk over the glottis into the larynx of unsensitised conscious guineapigs was for all intents and purposes without clinical effect On the other hand, a small amount of milk dropped into the larynx of sensitised guineapigs resulted in a characteristic anaphylactic reaction often leading to death The reaction itself and the pathological findings in such animals were those of frank anaphylaxis and did not resemble those seen in human cot-death cases If, however, the guineapigs were lightly anæsthetised—an experimental condition used to simulate the condition of the sleeping child—milk introduced into the larynx had quite a different effect In the unsensitised guineapigs there was no untoward effect, and even in the sensitised animals there was a complete absence of the usual features of anaphylaxis seen in a conscious animal Very soon after introducing the milk preparations into the larynx of an anæsthetised sensitised guineapig, the animal stopped breathing without any signs of struggle Death sometimes occurred immediately, but the majority of animals took deep breaths at 10–30-second intervals for a variable period Death was preceded by a short period of more rapid breathing, each respiratory effort being shallower than the preceding one, until, with a final nose-twitching, the animal died Others lingered for 20–60 minutes before death took place, or normal respiration was gradually resumed This sequence of events became recognised as characteristic, and was reproducible on challenge of all the anæsthetised sensitised animals The pathological findings in the animals which died resembled those in human cot-death cases

In the present paper we have tried to relate our experimental results more directly to the condition in man (1) Sera from actual cases of cot death have been examined for their level of milk antibodies, as shown by the coated tanned red-cell test, in order to see if the distribution of levels is higher, as would be expected, than in randomly selected infants of comparable age (2) To test our hypothesis that the aspirated milk proteins originate as a regurgitation from the stomach, experiments have been performed on anæsthetised sensitised guineapigs in which the stomach contents recovered from cases of cot death were introduced into the respiratory tract Only stomach contents from infants known to have been bottle-fed at the time of death were used (3) Experiments have been performed to see if the individual milk proteins can produce a lethal effect (4) The pathological findings in guineapigs killed in this way are compared with those in cases of human cot death

Materials and Methods

These have been described in detail in two previous papers (Parish et al 1960, Gunther et al 1960)

Milk and Milk Proteins

As National dried milk powder is the product given to the majority of bottle-fed infants, it was employed as the source of milk proteins in our previous studies In the present work this product was again used as the sensitising antigen and the soluble proteins of the reconstituted powder used to coat the tannic-acid-treated red cells in the serological tests for milk antibodies

The isolated proteins of cow s milk—namely, casein, α-lact-albumin, and β-lactoglobulin—were prepared as described by Gunther et al (1960) and were kindly supplied by Dr R Aschaffenburg

Testing Sera for Antibodies

The method was basically the coated tanned red-cell technique of Boyden modified as described by Gunther et al (1960) The tanned red-cells were coated by exposing them to a 0 5% solution of protein antigen

Sensitisation of Guineapigs and Challenge

The guineapigs each received one intraperitoneal injection

---

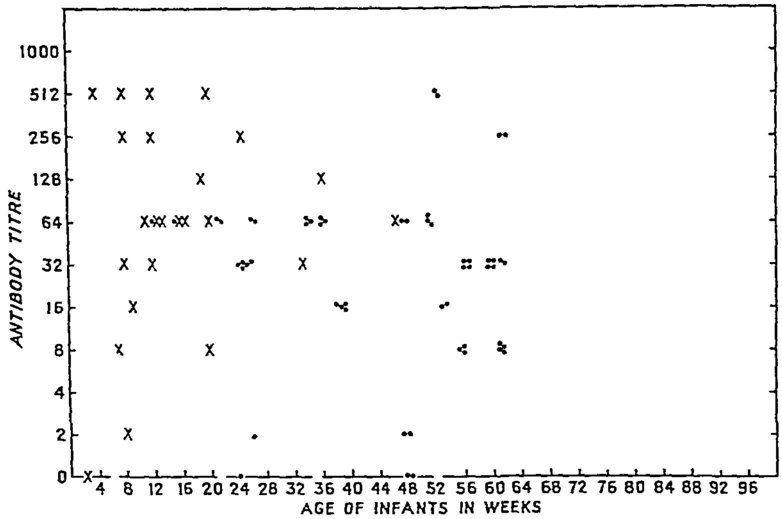

Fig 1—Titres of serum-antibody to cow's milk proteins at various ages in 24 'cot-death' cases (X) and in 286 normal infants (●)

A strict comparison of the two categories is not possible for the reasons stated in the test

of 1 ml reconstituted milk powder 2% w/v The inoculum consisted of the soluble and insoluble material

In experiments with human stomach-contents the animals were challenged on the 18th day after injection In experiments with milk proteins they were challenged on the 69th day

Anæsthesia

Pentobarbitone ('Nembutal') was used as the anæsthetic in a dose of 0 01 ml per 20 g body-weight given intraperitoneally The depth of anæsthesia was such that the corneal reflex was very weak or just absent and the pedal reflex still present This was usually achieved in 15 minutes after injecting the pentobarbitone

Challenge via the respiratory tract—This was designed to mimic, as closely as possible, the accidental inhalation of regurgitated stomach contents by the sleeping infant The method has been fully described and illustrated by Parish et al (1960) With the aid of a gag and an illuminated nasal speculum, the mouth was opened and the entrance to the pharynx exposed While the tongue was depressed by a thin metal spatula, the milk or other challenging antigen was introduced over the glottis from a specially shaped blunt needle attached to a syringe When the animal inspired through the mouth it was possible to see the epiglottis which was the guide to the site of injection With practice it was possible to deposit the milk drop by drop over the glottis so that it was inhaled even when the larynx was invisible to the operator This procedure caused the minimum amount of damage to the respiratory tract

Experimental Study

Serum Antibody Levels

Using coated tanned red cells Gunther et al (1960) tested the sera of 286 normal children aged 7–97 weeks (fig 1) Nearly all the sera contained measurable antibody to cow's milk proteins In distribution the mode fell around a titre of 64 Approximately 4% had a titre of 256, 1% a titre of 512, and one serum had a titre of 1000 The plot of serum titre against the age in weeks of the child is shown in fig 1

We have now tested sera from 24 cases of cot death for the titre of antibodies to cow's milk Only those cases of sudden death were included which, on the pathologist's report, could be considered as "cot-death" cases These infants were known to have been bottle-fed at the time of death, and milk was found in their stomachs at post mortem

The serum titres of antibody to cow's milk in the cot-death cases are also shown in fig 1 where the distribution can be seen in relation to that found in normal infants

The number of cases available so far is not sufficient for a final assessment, nor is the mode of selection in the two categories appropriate for a strict comparison between the serum levels in normal infants and in the cot-death cases In the first place approximately 32% of the normal infants were known to be mainly breast-fed at 6 weeks of age, while the cot-death cases studied were all bottle-fed at the time of death Moreover, the blood from normal infants was collected under ideal conditions and the sera frozen to −15°C within 5 hours of bleeding, while the blood from cot-death cases was obtained post mortem and often had considerable precipitates which had to be centrifuged out before testing However the high titres found in the sera of the majority of cot-death cases are in keeping with the possibility that, had these infants aspirated milk into their respiratory tracts, a lethal hypersensitivity reaction, as seen experimentally in guineapigs, might have occurred

We are not suggesting that the level of serum antibody is necessarily a measure of the degree of sensitivity, although for the type of anaphylactic reaction envisaged this cannot be excluded It does indicate, however, that the infants have received a considerable antigenic stimulation with cow's milk and are, for this reason, potentially sensitised to these proteins

Effect of Stomach Contents on Sensitised Guineapigs

In our previous experiments (Parish et al 1960) National dried milk was used as the material for challenge In the present paper we report a similar experiment but the material used was stomach contents from actual cot-death cases in which the infant's last feed had been from the bottle This was used because, in the hypothesis we put forward, we believe regurgitated stomach contents are the source of the aspirated material initiating the lethal reaction

In this experiment both sensitised and unsensitised (control) guineapigs were lightly anæsthetised with an intraperitoneal injection of pentobarbitone Approximately 15 minutes later, when the desired state of anæsthesia had been reached, 0 25 ml of a 1/2 dilution of stomach contents (0 125 ml of the original contents) was introduced into the larynx Stomach contents from 4 cases of cot death were used The tenaciousness of this material necessitated its dilution with an equal volume of saline to avoid mechanical obstruction of the respiratory tract of the guineapig, which is, of course, much narrower than that of the human infant The stomach contents were obtained from dead infants aged 2, 4, 8, and 22 weeks The larger lumps found in the stomach of the oldest child were first broken down in a Griffith grinder

TABLE I—CLINICAL EFFECTS OF INHALING STOMACH CONTENTS FROM HUMAN COT-DEATH CASES BY NORMAL AND BY PREVIOUSLY SENSITISED GUINEA-PIGS LIGHTLY ANÆSTHETISED TO SIMULATE SLEEP

In a review of the possible causes of sudden death in infancy, Barrett (1954) suggested that of such cases " perhaps the majority are due to the inhalation of regurgitated food into the lungs " The inhaled food might not cause death by directly obstructing the air-passages an amount of milk too small to cause immediate asphyxia might excite an inflammatory reaction accompanied by pulmonary œdema, or the absorption of undue amounts of milk derivatives into the blood-stream might cause a state of shock

Such effects of inhaled food or vomit, if they occur, might be due either to an inherent toxicity of the inhaled material when it enters the body by this abnormal route, or to an anaphylactic type of reaction resulting from antigenic sensitisation

We present some experimental evidence which suggests that the second, but not the first, of these two mechanisms is indeed a possible cause of sudden death in infancy The hypothesis is that some infants may be in a hypersensitive state from the development of antibodies to the proteins of milk absorbed from the alimentary tract Infants often regurgitate stomach contents while asleep, and should some of this material be aspirated into the respiratory tract of an infant which has become hypersensitive, the result might be fatal

There is no doubt that most infants fed on cow's milk develop antibodies to the proteins of the milk Gunther, Aschaffenburg, Matthews, Parish, and Coombs (1960) using a sensitive technique—the coated tanned red-cell test of Boyden (1951)—showed milk antibodies in normal children aged 7–97 weeks in a titre up to 1000 with a modal distribution around a titre of 64

There thus seems to be ample evidence that the majority of *infants* are *immunised* to some degree or other to the proteins of cow's milk, and the possibility exists that these or other types of antibody may sensitise the tissues of the infants Anderson and Schloss (1923) showed that in infants with some types of nutritional disorders, milk proteins were absorbed via the alimentary tract and that subsequently precipitins to milk protein could be shown in the infants' sera, and these antibodies could sensitise guineapigs passively to anaphylaxis According to Clein (1958), up to 6% of infants during the first few months of their lives are allergic to cow's milk

Parish, Barrett, and Coombs (1960) showed that administration of milk over the glottis into the larynx of unsensitised conscious guineapigs was for all intents and purposes without clinical effect On the other hand, a small amount of milk dropped into the larynx of sensitised guineapigs resulted in a characteristic anaphylactic reaction often leading to death The reaction itself and the pathological findings in such animals were those of frank anaphylaxis and did not resemble those seen in human cot-death cases If, however, the guineapigs were lightly anæsthetised—an experimental condition used to simulate the condition of the sleeping child—milk introduced into the larynx had quite a different effect In the unsensitised guineapigs there was no untoward effect, and even in the sensitised animals there was a complete absence of the usual features of anaphylaxis seen in a conscious animal Very soon after introducing the milk preparations into the larynx of an anæsthetised sensitised guineapig, the animal stopped breathing without any signs of struggle Death sometimes occurred immediately, but the majority of animals took deep breaths at 10–30-second intervals for a variable period Death was preceded by a short period of more rapid breathing, each respiratory effort being shallower than the preceding one, until, with a final nose-twitching, the animal died Others lingered for 20–60 minutes before death took place, or normal respiration was gradually resumed This sequence of events became recognised as characteristic, and was reproducible on challenge of all the anæsthetised sensitised animals The pathological findings in the animals which died resembled those in human cot-death cases

In the present paper we have tried to relate our experimental results more directly to the condition in man (1) Sera from actual cases of cot death have been examined for their level of milk antibodies, as shown by the coated tanned red-cell test, in order to see if the distribution of levels is higher, as would be expected, than in randomly selected infants of comparable age (2) To test our hypothesis that the aspirated milk proteins originate as a regurgitation from the stomach, experiments have been performed on anæsthetised sensitised guineapigs in which the stomach contents recovered from cases of cot death were introduced into the respiratory tract Only stomach contents from infants known to have been bottle-fed at the time of death were used (3) Experiments have been performed to see if the individual milk proteins can produce a lethal effect (4) The pathological findings in guineapigs killed in this way are compared with those in cases of human cot death

Materials and Methods

These have been described in detail in two previous papers (Parish et al 1960, Gunther et al 1960)

Milk and Milk Proteins

As National dried milk powder is the product given to the majority of bottle-fed infants, it was employed as the source of milk proteins in our previous studies In the present work this product was again used as the sensitising antigen and the soluble proteins of the reconstituted powder used to coat the tannic-acid-treated red cells in the serological tests for milk antibodies

The isolated proteins of cow's milk—namely, casein, α-lactalbumin, and β-lactoglobulin—were prepared as described by Gunther et al (1960) and were kindly supplied by Dr R Aschaffenburg

Testing Sera for Antibodies

The method was basically the coated tanned red-cell technique of Boyden modified as described by Gunther et al (1960) The tanned red-cells were coated by exposing them to a 0 5% solution of protein antigen

Sensitisation of Guineapigs and Challenge

The guineapigs each received one intraperitoneal injection

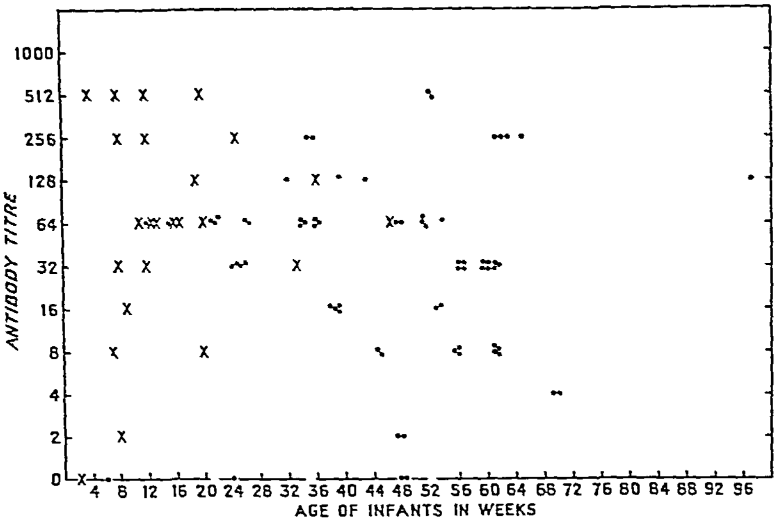

Fig 1—Titres of serum-antibody to cow's milk proteins at various ages in 24 'cot-death' cases (X) and in 286 normal infants (●)

A strict comparison of the two categories is not possible for the reasons stated in the text

of 1 ml reconstituted milk powder 2% w/v The inoculum consisted of the soluble and insoluble material

In experiments with human stomach-contents the animals were challenged on the 18th day after injection In experiments with milk proteins they were challenged on the 69th day

Anæsthesia

Pentobarbitone ('Nembutal') was used as the anæsthetic in a dose of 0 01 ml per 20 g body-weight given intraperitoneally The depth of anæsthesia was such that the corneal reflex was very weak or just absent and the pedal reflex still present This was usually achieved in 15 minutes after injecting the pentobarbitone

Challenge via the respiratory tract—This was designed to mimic, as closely as possible, the accidental inhalation of regurgitated stomach contents by the sleeping infant The method has been fully described and illustrated by Parish et al (1960) With the aid of a gag and an illuminated nasal speculum, the mouth was opened and the entrance to the pharynx exposed. While the tongue was depressed by a thin metal spatula, the milk or other challenging antigen was introduced over the glottis from a specially shaped blunt needle attached to a syringe When the animal inspired through the mouth it was possible to see the epiglottis which was the guide to the site of injection With practice it was possible to deposit the milk drop by drop over the glottis so that it was inhaled even when the larynx was invisible to the operator This procedure caused the minimum amount of damage to the respiratory tract.

Experimental Study

Serum Antibody Levels

Using coated tanned red cells Gunther et al (1960) tested the sera of 286 normal children aged 7–97 weeks (fig 1) Nearly all the sera contained measurable antibody to cow's milk proteins In distribution the mode fell around a titre of 64 Approximately 4% had a titre of 256, 1% a titre of 512, and one serum had a titre of 1000 The plot of serum titre against the age in weeks of the child is shown in fig 1

We have now tested sera from 24 cases of cot death for the titre of antibodies to cow's milk. Only those cases of sudden death were included which, on the pathologist's report, could be considered as 'cot-death'' cases These infants were known to have been bottle-fed at the time of death and milk was found in their stomachs at post mortem

The serum titres of antibody to cow's milk in the cot-death cases are also shown in fig 1 where the distribution can be seen in relation to that found in normal infants

The number of cases available so far is not sufficient for a final assessment, nor is the mode of selection in the two categories appropriate for a strict comparison between the serum levels in normal infants and in the cot-death cases In the first place approximately 32% of the normal infants were known to be mainly breast-fed at 6 weeks of age, while the cot-death cases studied were all bottle-fed at the time of death Moreover, the blood from normal infants was collected under ideal conditions and the sera frozen to −15°C within 5 hours of bleeding, while the blood from cot-death cases was obtained post mortem and often had considerable precipitates which had to be centrifuged out before testing However the high titres found in the sera of the majority of cot-death cases are in keeping with the possibility that, had these infants aspirated milk into their respiratory tracts, a lethal hypersensitivity reaction, as seen experimentally in guineapigs, might have occurred

We are not suggesting that the level of serum antibody is necessarily a measure of the degree of sensitivity, although for the type of anaphylactic reaction envisaged this cannot be excluded It does indicate, however, that the infants have received a considerable antigenic stimulation with cow's milk and are, for this reason potentially sensitised to these proteins

Effect of Stomach Contents on Sensitised Guineapigs

In our previous experiments (Parish et al 1960) National dried milk was used as the material for challenge In the present paper we report a similar experiment but the material used was stomach contents from actual cot-death cases in which the infant's last feed had been from the bottle This was used because, in the hypothesis we put forward, we believe regurgitated stomach contents are the source of the aspirated material initiating the lethal reaction

In this experiment both sensitised and unsensitised (control) guineapigs were lightly anæsthetised with an intraperitoneal injection of pentobarbitone Approximately 15 minutes later, when the desired state of anæsthesia had been reached, 0 25 ml of a 1/2 dilution of stomach contents (0 125 ml of the original contents) was introduced into the larynx Stomach contents from 4 cases of cot death were used The tenaciousness of this material necessitated its dilution with an equal volume of saline to avoid mechanical obstruction of the respiratory tract of the guineapig, which is, of course, much narrower than that of the human infant The stomach contents were obtained from dead infants aged 2, 4, 8, and 22 weeks The larger lumps found in the stomach of the oldest child were first broken down in a Griffith grinder

Scale of severity of clinical effects

D=death.

——— =severe respiratory embarrassment just insufficient to be fatal

—— =definite clinical disturbance but not severe.

— =one or two signs of respiratory embarrassment but always mild.

— =no response

In the unsensitised guineapigs no deaths, and in the great majority of cases no effects, were observed On the other hand most of the sensitised animals exhibited the syndrome already described and died silently, without any struggle, and in a very short time Three animals recovered after a protracted period during which there were long spells of apnœa interrupted only by occasional weak gasps One of the sensitised animals was apparently unaffected The results are summarised in table I

Effect of Milk Proteins on Sensitised Guineapigs

In our earlier report (Parish et al 1960) we recorded the level of milk antibodies and the clinical sensitivity to challenge with milk at 17, 38, 64, and 92 days after a single sensitising injection Although in some animals the level of serum-antibody appeared to fall with the passage of time the animals were as sensitive clinically to the aspiration of milk on the 92nd day as they were earlier We wished to see if a similar lethal reaction could be produced by the individual component proteins of cow's milk

The guineapigs were sensitised as before by injecting intraperitoneally 2% w/v reconstituted National dried milk in a dose of 1 ml On the 69th day they were challenged via the respiratory tract while under light anæsthesia with 0 25 ml of (*a*) the soluble proteins in 10% w/v reconstituted milk powder (approximately 1% soluble proteins), (*b*) 1% casein, (*c*) 1% α-lactalbumin, or (*d*) 1% β-lactoglobulin The day before challenge each animal was bled and the serum subsequently tested for antibodies to reconstituted dried milk, and to the component protein with which the guineapig was challenged

The results of the serological tests, and the clinical effects on challenge are recorded in table II Casein, as might be expected, proved to be as effective as whole milk in producing lethal reactions In one of the previous papers (Gunther et al 1960) similarly sensitised guineapigs tested 17 days after injection had antibodies to α-lactalbumin but none to β-lactoglobulin In the present experiment no antibodies could be shown to α-lactalbumin 69 days after injection Clinically only very mild reactions were produced on challenging with α-lactalbumin, but with β-lactoglobulin the reactions were as severe as with casein or whole milk

* Made up 10% w/v—approximately 1% soluble protein

† A 1% solution

Of thirty unsensitised (control) anæsthetised guineapigs challenged with soluble or insoluble milk preparations (Parish et al 1960) no reaction was observed in twenty-six—one showed a very mild reaction and two a moderate reaction One animal died but on subsequent investigation its serum was shown to contain what appeared to be a naturally occurring antibody to cow's milk proteins to a titre of 16

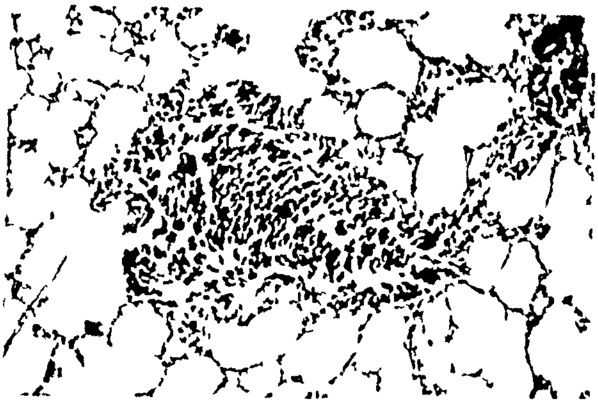

Fig 2—A bronchiole of anæsthetised sensitised guineapig which died soon after the introduction into its trachea of 0 25 ml of diluted (50%) stomach contents from a case of cot death (Hæmatoxylin and eosin ×120)

The bronchiole is so full of desquamated epithelial cells that in the photograph it is scarcely recognisable

We have thus shown that lethal reactions can be produced with casein and β-lactoglobulin On the other hand only mild reactions were obtained with α-lactalbumin However, further guineapigs will have to be tested at different periods after sensitisation before this protein can be considered less noxious than the other two

Pathological Findings in Sensitised Guineapigs

The histopathology of the lungs of sensitised guineapigs which died after inhalation, when anæsthetised, of total reconstituted dried milk, or its soluble or insoluble fractions, has already been described (Parish et al 1960) All the changes observed in the lungs of similarly sensitised guineapigs which died after the inhalation of casein or β-lactoglobulin closely resembled those in the earlier experiments *In those sensitised animals challenged with β-lactoglobulin or casein, the chief* features were generalised congestion with occasional areas of partial collapse, and serous exudate or œdematous transudate Cellular infiltration in the œdematous areas, or in the peribronchial, or periarteriolar connective tissue consisted chiefly of mononuclear cells Many of these were macrophages with variable numbers of lymphocytes and, in some animals, plasma-cells, but there were few polymorphonuclear cells A common finding was the desquamation of large numbers of single, intact, apparently normal, epithelial cells of the bronchial wall into the lumen of the small bronchioles

The histopathological changes in the lungs of sensitised anæsthetised guineapigs which had died as a result of inhaling small amounts of the stomach contents obtained from cot-death cases were similar to those observed in sensitised animals inhaling milk Generalised congestion was usual, but there was only an occasional small area of œdema and little cellular infiltration The infiltrating cells were chiefly macrophages, though there was an increased number of polymorphonuclear leucocytes—more than observed in animals challenged by milk The majority of the leucocytes were eosinophils, and in some preparations they were found also in the peribronchial connective tissue There was some evidence that the bronchioles and arterioles had undergone contraction, but further study of this feature is required Many of the medium-sized and smaller bronchioles contained large numbers of desquamated cells, sometimes these completely filled the lumen (fig 2) Bronchioles thus affected could be found in all the lung material, but the number varied from animal to animal The trachea was usually congested and in some cases infiltrated by eosinophils, the epithelium of the trachea was not desquamated

The unsensitised—i e, normal anæsthetised control guineapigs which had inhaled the stomach contents obtained from the same human subjects, and subsequently killed by an

HE outlook after myocardial infarction has usually 1 assessed by comparing results of treatment in a few e patients with a simultaneous control series The ively small numbers in clinical trials (and in a disorder uch variable course 100 must be regarded as small), lead to chance results which are deceptive. In most he trials unequivocal diagnostic criteria have been anded, and these have usually been the characteristic ires that have been recognised for the past thirty s A positive diagnosis is almost irrefutable, and the errors are those of omission (Paton 1957) The ies of Björck et al. (1958) do not support the idea that at improvements in finesse of diagnosis have added nts with improved survival prospects Before long- anticoagulant therapy was introduced there were v studies on prognosis, and to neglect them would be obbish ' (Björck 1960)

e begin by reviewing the more important of these w-up studies to reveal the factors on which prognosis depends We are not concerned with the vexed problem of immediate mortality in the acute phase (Morris et al 1952), but with the survival prospects of those who have recovered from a single recognised acute infarction Though we shall mention some studies which deal with first or subsequent infarctions, and some which include angina, these are mainly used to provide supporting data on certain aspects

Wider appreciation of the methods of calculating life-tables has compelled the discarding of many older studies where survival was estimated on patients who had died, and the recalculation of others such as the data of Sigler (1951) who tabulated the dead and living separately Other papers were discarded because of inadequate information on important influences such as age

Factors Influencing Prognosis

The more important studies on prognosis are summarised in tables 1a, 1b, and 1c, and are illustrated in figs 1 and 2 The studies on myocardial infarction total 5398 patients, while the series including angina adds another 8639 While five-year survival tends to cluster round 65–70%, it will be shown that survival is much better in younger patients who have made a good recovery and worsens with increasing age in those with extensive lesions, and with complicating conditions like hypertension and diabetes

Age and Sex

There is a striking difference between survival prospects in Waldron and Constable's (1950) series and those of Eckerström (1951) the average age in the former was 51 5 but the average age (66 7) of the latter series was obviously weighted by a substantial number in the eighth decade or over Inspection of table 1 shows a general trend to higher five-year mortality

* This figure applies to cases described as "coronary insufficiency"

† This figure applies to all cases of coronary heart-disease without evidence of acute infarction

These studies show that the chances of survival following acute infarction can be assessed by consideration of age, sex, economic status, severity of the attack and degree of recovery, and complicating diabetes or hypertension The slightest degree of unintentional bias in the selection of patients for treatment and control groups could profoundly influence the results

Anticoagulant Treatment

The use of dicoumarol and phenindione in the treatment of acute myocardial infarction has been followed by a significantly lower mortality during the acute phase Wright et al (1948) reported the results of the American Heart Association's trial which showed a 24% mortality in the control series compared with a 15% mortality in the treated In patients under 60 the crude death-rates were the same in both groups, but there was less nonfatal thromboembolism in the treated patients They accordingly advocated the use of anticoagulants in the acute phase, especially in patients aged 60 and over Feldman et al (1952) studied 189 patients, and did not find that mortality was reduced, or that thromboemboli were less frequent in a series of treated and control patients matched for age, sex, and cardiovascular status The work of Gilchrist and others in this country (Gilchrist and Tulloch 1956) has established a place for anticoagulant treatment in the acute phase, particularly to reduce thrombosis on the venous side, and subsequent emboli in the pulmonary and systemic circulations That these are the effects of anticoagulants is postulated by Bjerkelund (1957), but he cautiously states that "one is hardly justified in concluding that this form of treatment also prevents arterial thrombosis, including coronary thrombosis itself, which in many respects is thought to be of a different nature and related to other pathogenetic factors"

The claims of improvement in prognosis from acute-phase treatment have led to widespread interest in long-term treatment, but, in the absence of critical and controlled work, it is difficult to define the place of anticoagulants in preventing myocardial infarction Gilchrist (1960) admits that in our present experience, and in the absence of all the desirable evidence, the case for long-

publications shows that—although the results are gen described as favourable—it is exceedingly difficult t the figures given as a basis for a definite concl regarding this therapy"

Control Series

We have shown that the prognosis for survival recovery from myocardial infarction is influence many factors affecting the results of any trial u critically matched in control and treated groups S times published results appear convincing unti control group is analysed Bjerkelund (1957) and M R C (1959) studied patients who were ma accurately, but most other papers are less reliable

Lack of an Adequate Control Group

Keyes et al (1956) showed that mortality of treated patients was 8 4% in four years compared 41% in the same period in the untreated with infarctions No facts are given about the age, se history of either the control or treated group, the fo being two-and-a-half times as large as the group trated patients, suggesting some selection

Tulloch and Wright (1954) studied a very small g (32 patients after the late phase of myocardial infarc with a fifteen-month mortality of 6 2%, but they gav facts about their patients, and so it is impossible to a the results, and, in any case, this mortality does not significantly from the upper range of large untre series (fig 8)

Ensor and Peters (1959) used a "pseudo-cont group—i e, a group of patients who had had antico lants for some time but who had discontinued treatm The only fact given about the patients is the severity myocardial infarction in the treated group, but authors are cautious in their claims as they only r a 79% five-year survival in treated patients ag 70 7% in the "pseudo-controls"

Nichol et al (1958) studied the effect of anticoag treatment in patients with impending infarction,

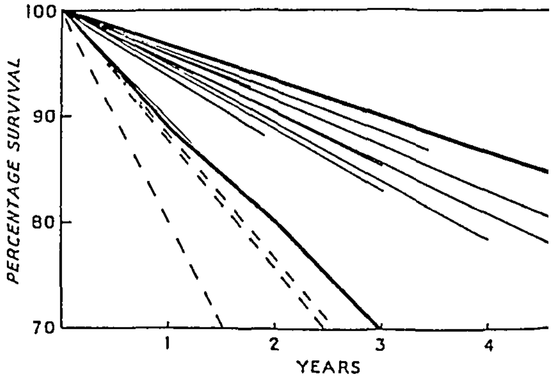

Fig 8—Treated series compared with untreated

The general prognosis derived from fig 1 lies between the lines The survival of treated patients (continuous lines) is s using survival table data or percentage survival at the end o average length of treatment The treated series from above are (1) Tandowsky (1959), (2) Muri (1956), (3) Ensor and P (1959), (4) Suzman (1959), (5) Ødegaard (1958), (6) Tulloch Wright (1954), (7) Bjerkelund* (1957), (8) Waaler† (

with one or two previous infarctions They used controls, however, patients from their records who been previously followed up without any treatment ney also named a group of patients who abandoned -term treatment It is significant to note that 14% the deaths in this group occurred within one month stopping anticoagulants But none of the groups matched and the average period of follow-up in each Their treated patients showed an 88% vival after an average period of 1 87 years, well within ns of past experience (fig 8)

Suzman et al (1955) present formidable figures to that patients on long-term treatment do better than treated during the acute phase only Although this a careful study, the chief drawback to their results is " the final decision for long-term treatment was left the patient " Economic factors obviously entered into selection, and the results of treatment were a five-year val of 76 1% against 45 6% in the untreated cases uzman (1959) has kindly allowed us to see his unpub- figures which show that recurrent infarction ccurred only slightly less often (34 7% against 43 2%), its mortality was less (40 5% against 74 8%) in long-treatment patients than in the short-term group results, however, must be seen against the background of the selection of patients and the age-distribution of the groups, 31% of the patients in the short-term group were over 70, compared with only 20% in the -term group

Tandowsky (1959) does not mention his patients' status, except to describe the 70 controls as " a like group " in whom the mortality (53%) was four times that of the treated (13%), the average duration of treatment was three years and five months

Use of Retrospective Studies to Provide Control Groups

Some papers which have given encouraging figures for urvival in patients treated with long-term anticoagulants not had a concurrent control series Some writers have compared a series of patients treated in one country ith a series reported in a different country some years efore. Thus, Muir (1956) who had a 7 5% mortality an average exposure to risk of twenty-one months ompared his results with those of Parker et al (1946) which were later included in the total series of Block et al 1952), both reporting an exceptionally high (19 and 16% espectively) first-year mortality Waaler (1957) who chieved a 17% three-year mortality, also used as controls he data of Block which are seen to be much worse than hose of Sigler or Seim (table Ic)

Tanzi and van Ness (1957) compared their mortality f 6 1%, in a sixteen-month average, with those " so far eported " Toohey (1958), who had an 11 6% mortality t eighteen months, used as controls patients who had een followed up after myocardial infarction in the same nd another hospital during the seven years before long-erm anticoagulants this series had a 33% two-year mortality Toohey did not mention either age or sex among his patients, and so it is not easy to accept the laim that his results are " statistically significant " His ontrols, who had a much higher mortality than usual, may have been an aged group, and his treated patients were not matched with the controls in any way

dmission to Treated Group and Follow-up Care

Tanzi and van Ness (1957) and Keyes et al (1956) mited their treatment to those who could cooperate The former achieved 6 1% mortality in sixteen months while the latter had a 9 9% mortality between one and thirty-eight months of observation, results which lie within upper range of life expectation as shown in fig 1 The striking five-year survival, 83%, which Morris et al (1952) reported in medical practitioners, demonstrates the part played by intelligence, social status, and careful follow-up in survival after myocardial infarction Constant supervision is certain to ensure earlier treatment of symptoms which may arise, and this is the only way in which the control group of patients in Bjerkelund's (1957) admirable study differed from the treated group The latter were seen every one to three weeks against the three to four monthly intervals between the visits of control patients

Results of Treatment

Although many reports have an inadequate control series, they give valuable facts about survival in the treated patients

Survival of Patients

Many of the earlier papers included a few patients with myocardial infarction, and a larger series treated with long-term anticoagulants for thromboembolic disease, and so are not satisfactory for survival data Tulloch and Wright's (1954) and Muir's (1956) figures have already been discussed Nichol and Borg (1950) treated 78 patients for an average of fifteen months and reported a 15 3% mortality, which is less good than the average (fig 8) Ødegaard (1958) treated 117 patients, of mean age 58 9 for a total of 343 patient-years, and found a mortality-rate of 4 87% per year—a little better than average but not outside the range of untreated patients There was a 10% mortality in 735 patrents with one infarction, studied for an average of twenty months by Nichol et al (1958) they also reported an overall mortality rate of 12% in 1091 patients with impending one or two infarctions, studied for an average of 22 4 months Both these figures are within " untreated " expectation Manchester (1957) expresses his results as the fatality, and number of recurrent infarctions per 100 patient-years, these figures were 0 56 and 2 73 respectively A survival table cannot be made from his data He had twice as many patients with heart-failure requiring digitalis (33%) in his control group as in his treated group (15 6%) The five-year survival of 76% in Suzman's (1959) treated patients may well reflect the better social status of his patients

The chief interest in the reports of Bjerkelund (1957) and the M R C (1959) is the difference which is shown between the control and treated patients during the early months of long-term treatment Bjerkelund (1957) stated that the " force of mortality " seemed to be largest initially in the control group, and that the treated patients—but only those under 60—did not show this initial excess mortality It is noteworthy that in both Bjerkelund's and the M R C series, most of the excess deaths in the controls took place in the first three months after infarction Bjerkelund reported no statistical difference between the " force of mortality " in the treated and control group at any age, a year and more after infarction (see figs 5 and 6 of his monograph) The M R C trial showed a similar trend, and although 19 of the 28 deaths in the low-dosage group occurred in the first six months compared with only 9 of the 17 deaths in the high-dosage group " the difference in the death rate was appreciable only during the first three months of the follow-up period " These results are best demonstrated by the death-rates per 100 man-months of exposure during the first year

Period	*Low dosage*	*High dosage*
Less than 3 months	2 7	0 8
3-6 months	1 7	1 1
6-9 months	0 8	0 5
9-12 months	0 0	0 8

While both these reliable reports show similar results, the efficacy of anticoagulant drugs was only transient Suzman (1959) and Manchester (1957), however, report sustained improvement of prognosis, and so these four important protagonists are far from agreement on the reasons for their advocacy of long-term treatment

No reported series shows that anticoagulant treatment in any way affects the pattern of an increasing mortality with age, or benefits older patients This is thoroughly borne out by Bjerkelund's (1957) results with his older (over 60) patients, whom treatment did not benefit Similarly, the difference between the low-dosago and high-dosage groups of men aged 55 and over was less marked than that in men under 55, which itself did not reach the 5% level of significance (M R C 1959)

These results, and those which have been given above, show that it is probably only in the acute and healing phases of myocardial infarction that anticoagulant treatment may be effective in increasing survival, but even this is not yet statistically proven Long-term anticoagulant prophylaxis beyond about two months after infarction cannot yet be justified by adequate evidence

In small numbers of patients—and we must count the M R C and Bjerkelund series as small—there are obviously possibilities of great variability indicated by "highly significant" results diminishing with the passage of time to statistical "insignificance" in both series That chance could readily operate to account for the results is borne out by the recent work of MacMillan et al (1960) In a statistically randomised series of 27 treated and 23 untreated patients, they had 8 deaths in the treated as against none in the untreated "controls"

Recurrence of Infarction During Treatment

The difficulties of establishing this diagnosis have already been mentioned, and the papers which report the results of treatment are not precise in defining the criteria for a recurrence Bjerkelund (1957) alone classifies his patients into those with definite, very probable, and probable recurrences, and he points out that the diagnosis could not be established with equal certainty in all cases However, the diagnosis of his recorded instances was definite in 63 5% of treated, and in 76% of untreated patients He is careful to state that cases of sudden death were only included as recurrent infarcts if definite signs of a fresh infarct were found post mortem Thus, his criteria differ from those of the M R C report (1959) in which all cases of sudden death were attributed to recurrent infarction Manchester (1957) does not mention the criteria for recognising a recurrence These divergences explain the varying results of table III, where the incidence and mortality of recurrences in treated patients are shown. The apparent tendency towards a lower rate of reinfarction in the treated patients is open to critical doubt on account of the above difficulties of controls and diagnosis.

Certain facts must be emphasised which arise from this study of reinfarction Bjerkelund (1957) makes a thorough study of the "force of recurrence" in his control group and shows a definite "excess of recurrences" in those under 60 during the first six months—but shows that this is not significant in the patients more than 60 years old Moreover, after twelve months he can find no statistical difference between the "force of recurrence in the treated and control groups, and he finds that anticoagulant therapy has not given much protection to those with a high "force of recurrence"—i e, those with a previous recurrent infarction He claims that during the observation period two-fifths of the recurrent infarctions and at least half of the deaths due to recurrences were prevented by dicoumarol treatment His most significant differences, however, were either in the first month of observation (i e, near the acute phase) or in patients over 70

The M R C (1959) data on recurrent infarction differ from those of Bjerkelund in suggesting that a disparity in infarct-rate between high-dose and low-dose patients continues into the second year of follow-up Although there were fewer cases of recurrent infarction among the treated, 17 out of 24 died from their recurrence, against 29 out of 60 in the low-dose group

A reduced incidence of recurrent infarction in treated patients was also reported by Manchester (1957) and his results appear to be formidable evidence, but he did not give details of the patients studied, nor any criteria for the diagnosis of a recurrence A large number (157) of his patients abandoned treatment, and these may have weighted survival in those continuing treatment towards a better prognosis, with fewer recurrences, as the M R C report suggests

Suzman (table III) also found a slightly lower rate of reinfarction in his long-term treated patients, especially in those whose previous infarction had been severe However, the mortality of recurrent infarction was higher in the control group (49 4% against 27 6%) It is noteworthy that the mortality in Suzman's "treated" recurrences was about half that in the M R C series where it was remarkably high (75%) Bjerkelund (1957) found that patients with a mild previous infarction had fewer recurrences, whereas Suzman (table III) found the reverse Recommendation of long-term anticoagulants is thus based on widely divergent findings

TABLE III—RECURRENT INFARCTION IN TRIALS OF TREATMENT

Author	Number of patients		Period of study (years)	Recurrence of infarction			
	Control	Treated		Control		Treated	
				Incidence (%)	Mortality (%)	Incidence (%)	Mortality (%
Keyes et al (1956)	231	121	2	38 0		2 0	
Bjerkelund (1957)	118	119	3	40 (*a*)	41 6	22 (*a*)	34 6
Manchester (1957)	200	204	10	31	53 0	14 2	20 6
Nichol et al (1958)		1091	1 87			10 75 (*b*)	66
Medical Research Council (1959)	188	195	3	27 5	46 5	12 3	75
Suzman (1959)	216 (*c*) mild	55	10	32 8	19 4	34 5	27 6
	298 (*c*) severe	115	10	50 7	61 4	31 8	38 3

(*a*) Includes cases classified as definite, very probable, and probable myocardial infarction
(*b*) Includes cases described as ventricular fibrillation or cardiac arrest (i e, sudden death)
(*c*) Refers to severity of first attack of infarction

eturn to Work

It has already been shown that many patients are able return to work, and to stay at work after recovery myocardial infarction without long-term treatment. is disappointing, therefore, that Bjerkelund (1957) d that only slightly more treated than control patients d to work. The small difference between the two ups probably depended upon more elderly patients among the controls. Bjerkelund states that the "difference hardly gives reason to believe that the treatment has influenced the patient's ability to work." The M.R.C. 1959) found that there were slightly more men at work n the treated group (83% against 71%), but the proportion without dyspnœa was the same (66% and 67%). This s the more remarkable as the 31 of the "untreated" vivors had had an additional recurrent infarction. Muir (1956) reported that 79% of treated patients were work, a figure in agreement with the M.R.C. treated and untreated groups, and thus hardly to be claimed as a erapeutic success.

A patient's return to work will in part be determined by his symptoms. A common symptom which can limit lity to work is cardiac pain, which has been reported be less frequent in patients treated with anticoagulants. We wish, however, to repeat Bjerkelund's (1957) statement that "cases of angina pectoris often have spontaneous fluctuations, and this makes assessment of prophylactic therapy very difficult."

Manchester (1957) found that 38 of 74 treated patients had less cardiac pain, compared with only 20 of 72 control patients. Similar figures were given by Tandowsky (1959) for the abatement of coronary insufficiency, and Waaler (1957) found that 8% of his series of treated patients with angina pectoris were wholly relieved, and 12% were partially relieved of pain. The M.R.C. (1959) reported that the absence of anginal pain uggested a slight superiority among the treated (64% against 2%) over three years of study. Bjerkelund (1957) meticulously ubdivided his patients according to their grade of cardiac ain, but was not convinced that dicoumarol had any "definite" prophylactic effect against this symptom.

Thromboembolism

The prevention of venous thromboembolism after the initial acute phase does not receive much prominence in any report, and it is evident that it is not very important clinically after the acute phase, though when it is recognised, the mortality is high.

Manchester (1957) reported 35 cases (17·5%) of whom 16 45·7%) died in his untreated group, against only 5·8% with 14·2% mortality in his treated patients. Bjerkelund (1957) ound extracardiac thromboemboli in only 2 of his control group, and in none of his treated group. Suzman (1959) ound thromboembolism three times more frequently in his untreated patients. Only 1 case is mentioned with a fatal cerebral embolus in the M.R.C. low-dosage group. It seems ikely that patients on anticoagulants are protected from venous hromboembolism (Sevitt and Gallagher 1959).

There is adequate postmortem evidence, however, that coronary arterial thrombosis can, and frequently does, develop in patients under expert anticoagulant control. Fresh coronary-artery thrombosis was found at necropsy n 58% of Bjerkelund's untreated patients, and, post mortem, in 26% of his treated patients. Capeci and Levy 1959) were not impressed by any diminution of thrombus ormation in treated patients who came to necropsy.

ndications for Treatment

Two different opinions are held about choice of patients or, and duration of, treatment. Nichol and Fasset 1947) decided to use anticoagulants for patients with recurrent infarction. Wright et al. (1954) and Suzman et al. (1955) also reported that this type of patient might benefit from treatment. The M.R.C. (1959) found that a lowering of the infarction-rate appeared most clearly in those in whom the risk of recurrent infarction was high, in younger males, and in those with more than one infarct. On the other hand, Bjerkelund's results indicated that there was no benefit from treatment in patients who had had more than one infarct; he would recommend treating all, or a large number of, patients for six months or a year, but not thereafter. The M.R.C. report, however, recommends that "continuous" treatment should be given as this can make a useful, if limited, contribution in the aftercare of patients who have recovered from the acute phase of myocardial infarction, in spite of their own evidence that the regime is of little value after six months.

Discussion

At the beginning of this paper, we showed that patients who survive the acute phase of a myocardial infarction have a five-year survival-rate of about 66%. This figure has varied according to the type of patient who has been followed up, ranging from above 80% in the doctors studied by Morris et al. (1952) to 30% in Eckerstrom's (1951) elderly patients. We have mentioned the remarkably good five-year survival figures for patients who make a complete clinical recovery, or who are young at the time of their infarction. All this evidence shows that myocardial infarction may often be followed by long survival. The various factors which affect prognosis have been documented in order to give a background of experience against which the results of long-term prophylaxis may be reviewed.

In studying the published reports on anticoagulant prophylaxis, we have become critical of the controls, who have often been at, or below, the lower extreme of prognosis found in untreated patients, while the treated fare no better than those in the upper range of survival prospect (fig. 8). The careful studies of Bjerkelund (1957) and of the M.R.C. (1959) have been a constant source of valuable data, but there is surprisingly little work of similar calibre in other studies.

Despite many claims, the evidence that long-term anticoagulants prevent recurrence, or reduce mortality, after the acute phase of infarction is still inadequate. Most of the benefits reported by Bjerkelund and by the M.R.C. working party occurred in the first few months—i.e., while patients were still recovering from the acute event. If the action of the drugs is to prevent arterial thrombosis, there is no reason why this prophylactic action should cease after a few months, and it may well be that the early benefits reported in the Bjerkelund and M.R.C. series are in fact related in some way to the early healing phase of the actual infarction. Another possibility is of harm to the controls from sudden termination of acute-phase treatment.

It seems possible that most of the benefits which have been reported in the acute phase of infarction are related to the efficacy of the drug in limiting venous thrombosis and preventing pulmonary embolism; most reports are consistent in this respect. The recent studies by Sevitt and Gallagher (1959) on prophylaxis of venous thrombosis with phenindione in patients with fractured femora are most encouraging. The apparent failure of the same measures to prevent coronary occlusion is all the more disappointing. Antiprothrombin drugs have also failed in cerebrovascular occlusive disease (Marshall and Shaw

1960), and in occlusive arterial disease of the legs (Singer and Rob 1960)

Venous and arterial thromboses probably differ considerably in their pathogenesis Venous thrombosis is undoubtedly promoted by stagnation in veins of the calf, often subjected to prolonged mechanical pressure in bed in debilitated patients Arterial thrombosis, on the other hand, is based on underlying disease of the arterial wall—atheromatous plaques and ulcers, which can liberate local tissue thromboplastins into the blood-stream, which in turn may be retarded by upstream narrowing of the vessel Ischæmia and myocardial infarction have been reported in patients with hæmophilia (Boivin 1954, Borchgrevink 1959, Stewart and Acheson 1957) The development of arterial occlusions in these patients reinforces the importance of local release of thromboplastin from the damaged intima as a crucial event in the changes leading to thrombosis, even of hæmophilic blood (Astrup et al 1959) Mural thrombi over infarcts form with almost equal frequency in patients on anticoagulants as compared with controls (Gilchrist and Tulloch 1956) Such observations raise serious doubts on the usefulness of anticoagulants in preventing local thrombosis on damaged arterial intima

Any problematic benefit from anticoagulants in the prevention of thrombosis should be weighed against the considerable risk of hæmorrhage mentioned in most reports Lethal cerebral hæmorrhage occurred in 4 out of 118 patients in Bjerkelund's (1957) series, 2, and possibly 3, fatalities were also recorded from Newcastle (Fuller 1959) Quite apart from the risk of cerebral and other fatal hæmorrhages, morbidity can result from serious bleeding from anticoagulant treatment Anticoagulants may not avert arterial occlusion, and there is a real, and probably increased, risk of thrombosis in the period immediately after the drugs are stopped Various reports have suggested that sudden cessation of antiprothrombin drugs may be followed by arterial occlusion within a short time (Nichol et al 1958), 20 such instances are documented by Dinon and Vander Veer (1960) It is not impossible that this complication may have been responsible for the early high mortality, so near the end of acute-phase treatment, in both the M R C and the Bjerkelund control patients Hence, when anticoagulants have been used in the acute phase of myocardial infarction, their administration should be tapered off over a period of three to four weeks

Finally, it is well to remember that factors other than thrombosis also play a part in the production of myocardial infarction Among them are thickening of the atheromatous plaques themselves, subintimal hæmorrhage (Paterson 1936, Paterson et al 1957), and sudden falls of blood-pressure reducing perfusion of critically narrowed coronary vessels Furthermore, recurrent thrombosis may be responsible for a little more than half the ultimate death-rate in patients who have recovered from a cardiac infarction

Summary

The survival of patients after recovery from myocardial infarction, and the factors which influence prognosis, have been studied from reported series

There is broad agreement in the published data, totalling over 5000 patients (table 1a and 1b), that the prospect of five-year survival in cases under 60 ranges round 66%, being worse with increasing age and complications, and better with improving social circumstances and completeness of recovery

Long-term anticoagulant prophylaxis, as carried today, shows no evidence of improving life when compared with the prognosis in this large of " untreated " patients

Possible reasons for this inefficacy of long-term an coagulant prophylaxis are briefly discussed against background of contrasting mechanisms of arterial venous thrombosis The possibility should also be sidered that some of the early high mortality in " controls may be the result of sudden cessation of " treatment"

We are particularly grateful to Dr M M Suzman and Dr MacMillan for putting their unpublished data at our disposal

POTASSIUM IN THE TREATMENT OF CHOLERA

RAYMOND H WATTEN
B.A , M D Stanford
ROBERT A PHILLIPS
M.B E , M D Washington, St Louis, B S Iowa
MEDICAL OFFICERS, UNITED STATES NAVAL MEDICAL RESEARCH UNIT NO 2, TAIPEI, TAIWAN (FORMOSA)

Sir Leonard Rogers, in 1909, advocated the use of a hypertonic solution containing sodium chloride, calcium chloride, and 0 4 g (5 4 mEq) per litre of potassium chloride, for the treatment of cholera, but in 1916 he decided to omit potassium from the mixture because ' some physiologists consider it unnecessary and possibly harmful " In 1946, Govan and Darrow demonstrated a fivefold reduction in mortality from infantile diarrhœa when potassium was added to replacement solutions used parenterally Electrolyte studies by the United States Navy in the 1947 Egyptian cholera epidemic showed an excessive loss of potassium in the stools, hence it was recommended that potassium 6 7 mEq be included in each litre of intravenous solution used in the treatment of cholera (Johnson et al 1948) Chakravarti and Chaudhuri, in 1954, recommended giving potassium salts, when the acute diarrhœa of cholera had subsided, to hasten convalescence, providing that renal function was satisfactory Despite the above, a recent review of cholera therapy (Pollitzer 1957) does not mention the use of potassium in the treatment of the acute disease

The Study

During the 1958 cholera epidemic in Bangkok Thailand, eventeen patients with proven cholera were studied intensively during their acute illness For the first 24 hours nothing was allowed by mouth in order to relate the fæcal changes to changes in plasma-electrolyte composition Thus, during the irst 24 hours, fluids were given exclusively by the intravenous route. Meanwhile balance studies were made, and afterwards a diet of boiled eggs, rice gruel, milk, and water was given ad libitum The fæces and urine were collected and measured daily until the patient was discharged. A detailed report of this investigation, including methods and procedures, has been published (Watten et al 1959) While it is impossible from hese studies to calculate balance data for more than 24 hours fter admission, approximate potassium losses during the 2–4 days of diarrhœa may be calculated

TABLE I—MEAN HOURLY FÆCAL VOLUME AND ELECTROLYTE CONCENTRATION OF CHOLERA STOOLS COLLECTED OVER 24-HOURS

—	Volume (ml. per hr)		Electrolytes (mEq per l)			
	Mean	Range	Na	Cl	K	HCO₃
1 patients with fæcal volume over 125 ml. per hr	340	130–730	137	107	16 1	45 2
patients with fæcal volume under 125 ml. per hr	100	23–120	114	89	26 4	43 5

Patients with severe cholera had 24-hour fæcal volumes of –17 litres In these patients the total volume of diarrhœal uid during the 2–4 days of the disease was 10–35 litres During the 24-hour balance period, the mean potassium ontent of the fæces was 16 mEq per litre (table I), and otassium losses in fæces and urine averaged 158 mEq , with range of 50–245 mEq The total fæcal and urinary loss of otassium for the entire period of diarrhœa varied from 400 to 700 mEq , or, for a 50 kg man, the loss was 15–30% of the total exchangeable body-potassium, assuming this value to be 9 mEq per kg body-weight for a normal man (Edelman and eibman 1959)

Fæcal potassium concentrations vary inversely with fæcal volume (Watten et al 1959) Table I shows that patients with fæcal volumes in excess of 3 litres per day (125 ml per hour), had fæcal sodium and chloride concentrations which were nearly isotonic with those of the plasma, while the potassium and bicarbonate concentrations were higher than the plasma levels

With amelioration of diarrhœa and decrease in fæcal volume, the potassium concentration increased while the sodium concentration decreased, this is related to selective reabsorption of sodium in exchange for potassium in the lower ileum and large bowel, and it has been demonstrated experimentally by D'Agostino et al (1953) Paralytic ileus, with abdominal swelling and cessation of diarrhœa, was often seen in patients whom we studied during the 1958 Bangkok cholera epidemic

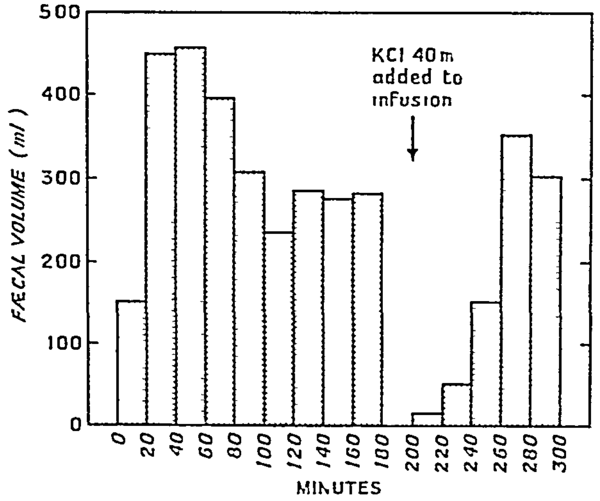

Fig 1—Fæcal volume measured at 20-min intervals during constant infusion (15 ml per min) of normal saline (4-140 min) and 2% sodium bicarbonate (140-240 min)

This complication, as Wilkinson (1943) pointed out, is probably responsible for the rare examples of so-called cholera sicca, in which death results from massive transfer of fluid into the bowel lumen without diarrhœa

Fig 1 shows 20-minute fæcal volumes in a patient during infusions of normal saline and 2% bicarbonate solution The drop in fæcal volume at 180 minutes was probably the result of potassium deficiency, because balances at that time revealed a loss of 165 mEq of potassium Fæcal volume increased after infusion of 40 mEq of potassium chloride, and then it remained constant with additional infusions of potassium The sequestration of a large volume of diarrhœal fluid in the bowel, caused by paralytic ileus, can be misleading and dangerous if fluid therapy is based on replacement of observed fæcal volume alone Utilisation of more accurate measurements of dehydration, such as plasma-specific-gravity determinations (Phillips et al 1950) will prevent such errors

During our cholera studies, alkalosis developed after treatment in four patients who had been given only 20–80 mEq of potassium (replacing about 10% of the deficit) during treatment (table II) The plasma-CO_2 content remained above 30 mEq per litre for as long as 7 days after the diarrhœa

TABLE II—ADMISSION AND CONVALESCENT PLASMA-CO CONTENT AND POTASSIUM LEVELS IN FOUR PATIENTS WITH SEVERE CHOLERA

Patient no	24-hr fæcal volume (ml per hr)	Plasma CO content (mEq per L plasma-water)		Plasma-potassium (mEq per l plasma-water)		Interval (days)
		Admission	Convalescent	Admission	Convalescent	
2	476	22 2	29 3	4 5	3 8	7
10	235	14 0	37 0	4 8	3 3	6
12	302	11 1	30 4	4 3	3 1	3
15	725	20 5	33 3	4 9	3 4	7

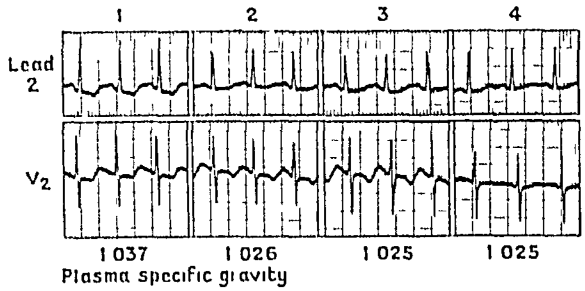

Fig. 2—Patient no. 6, 30-year-old Thai woman, 24-hour fæcal volume 7700 ml.

The tracings were made (1) on admission at 12.30 A.M. (plasma-CO_2 content 15 mEq. per litre), (2) at 2 P.M. after rehydration with 3 litres of normal saline, (3) at 4.30 P.M. after infusion of 500 ml. of 2% sodium bicarbonate solution (which raised the plasma-CO_2 content to 22 mEq. per litre), and (4) at 5.30 P.M. after infusion of 10 mEq. of potassium chloride in 1 litre of normal saline.

ceased, despite a normal diet. The data were not complete enough to indicate the pathogenesis of alkalosis associated with potassium deficiency in cholera, but they do indicate that a moderate alkalosis developed in several patients with serious potassium depletion, who had been treated with adequate quantities of saline and bicarbonate.

Serial electrocardiograms were taken during treatment of thirteen patients, but only five showed definite evidence of potassium deficiency either before or after the dehydration had been corrected with saline. Fig. 2 shows the changes in a patient with severe cholera. During the 5 hours before admission this patient passed seven watery stools, and was moderately dehydrated. The first tracing, taken 6 hours after the onset of the patient's diarrhœa, showed T-wave alterations in all leads. T-wave changes were less pronounced after saline and bicarbonate infusions, but they did not return to normal until potassium had been given. These changes were not caused by dehydration because plasma-specific-gravity values were within the normal range during the infusion therapy.

Discussion

Rational treatment of cholera requires knowledge of the altered physiology and chemistry of this disease. Such information has not been available until recently (Watten et al. 1959), and consequently therapeutic regimens have changed little since Rogers' recommendations of 50 years ago. There is universal agreement on the necessity for prompt replacement of water and salt, and the use of bicarbonate for the treatment of acidosis is accepted, but the risk of pulmonary œdema from overhydration (Chaudhuri 1950, Chakravarti and Chaudhuri 1954) is emphasised far more often than the danger of insufficient fluid replacement. Myocardial depression caused by potassium depletion rather than by rapid replacement of fluid may well be the important factor in the genesis of this complication. Death from "heart-failure" during convalescence (Baligh 1918) may also be due to deficit of potassium. Moreover, adjuvants to therapy (colloid plasma-volume expanders, cardiac stimulants, vasopressor agents, bacteriophage, antibiotics, &c.) continue to be given emphasis out of proportion to their value, and they detract from what should be the main line of cholera therapy—i.e., replacement of the lost water and electrolytes.

A lesser-known result of potassium depletion is renal tubular damage; vacuolisation of distal tubular cells, and damage to the collecting tubules, have been reported (Relman and Schwartz 1958, Holliday 1959). In a recent study of patients dying in uræmia after cholera, Benyajati et al. (1960) found microscopic changes in renal structure similar to those produced by potassium depletion. Ischæmic renal damage and uræmia due to delayed or inadequate fluid replacement is a frequent complication of cholera. Damage to kidney structure and impairment of function produced by potassium loss may contribute to renal failure in these cases.

Neuromuscular disturbances are a well-known complication of potassium deficiency. But there is only one report of transient potassium-depletion paralysis following cholera in eleven convalescent patients, this promptly subsided after potassium-chloride infusions had been given (Huang and Mao 1947). Instances are known of "secondary collapse" involving weakness, muscular twitching, and tetany during convalescence from cholera (Dr. C. Benyajati, personal communication).

Although plasma-potassium levels will eventually reflect potassium deficits, determinations made during the acute phase of cholera are of no value in establishing the need for potassium replacement. Data from our studies (Watten et al. 1957) indicate that plasma-potassium levels in acutely dehydrated patients were within the range of normal when corrected for plasma-protein concentration (expressed as mEq. per litre plasma-water). Furthermore, plasma-potassium values after rehydration were also within the range of normal. These findings indicate, as Scribner et al. (1958) concluded, that plasma-potassium concentration is independent of the volume of the extracellular space.

Saline solutions have been the foundation of cholera treatment. Table I shows that, for each litre of fæces lost from a patient with severe cholera, a litre of approximately isotonic saline will replace the salt lost. Theoretically, each litre of replacement solution should also contain about 16 mEq. of potassium and 45 mEq. of bicarbonate to replace these electrolytes.

The amount of potassium required to replace the deficits in acute cholera should be sufficient to prevent complications without producing toxicity. Ideally, measured potassium losses in urine and fæces would be exactly replaced, but facilities for this are rarely available in areas where cholera remains a problem, and even if they were the demands on time, personnel, and the laboratory during an epidemic would preclude their use except in the exceptional patient.

It therefore seems advantageous to add a small amount of potassium to each bottle of replacement solution. But the rapid infusion of 3–4 litres of a potassium-containing solution during the initial treatment of shock and collapse might increase the plasma-potassium levels too much, with the danger of heart-block and other conduction defects. Until further information is available it is advisable to use parenteral potassium only after the initial dehydration has been treated, and when maintenance solutions are given more slowly.

For the treatment of potassium depletion in infantile diarrhœa, Govan and Darrow (1946) recommended a solution containing 35 mEq. of potassium per litre which he never gave at the rate of more than 120 ml. per hour. In adults, Nadler et al. (1950) reported no untoward effects in treating the potassium depletion of diabetic acidosis and prolonged vomiting with an isotonic solution of potassium chloride (155 mEq. per litre) given intravenously at a rate of 290 ml. per hour (45 mEq. potassium per hour). But these infusion rates are far less than we have found necessary to maintain hydration in cholera patients, and an infusion-rate of 100 ml. per minute is for the rapid treatment of collapse during the period of rehydration

Without electrocardiographic or laboratory control, which is impossible during the treatment of large numbers of acutely ill cholera patients, a solution is needed that is safe under a variety of conditions. The addition of 10 mEq. (7.5 g.) of potassium chloride to 1 litre of saline should satisfy this need, and during an epidemic this solution could be used with safety in remote areas, even without medical supervision. It will replace at least half the initial potassium deficit in the average severe case, and it should prevent the major complications of potassium deficiency. As long as diarrhœa continues 10 mEq. potassium may be added to each litre of maintenance solution with impunity, even when the renal function is unknown, because potassium will continue to be lost in concentrations of 10–50 mEq. per litre of fæces (Watten et al. 1959). With cessation of diarrhœa, if renal function is not satisfactory, potassium should be discontinued. In uncomplicated cases, 10 ml. of a palatable mixture containing 100 g. each of potassium citrate, potassium acetate, and potassium bicarbonate per litre of water may be diluted and given by mouth three times a day as soon as nausea and vomiting cease.

From the electrolyte data reported in this paper, and from knowledge of experimental and clinical potassium depletion, one can conclude that the recommended addition of potassium should provide a more physiological approach to cholera therapy, diminish complications, and further reduce the mortality-rate.

> “One of the explanations why people in general are rather well satisfied by living and working in these regulated national communities of the Western World is undoubtedly that they do not notice the controls so much, or do not react so violently, as they are becoming accustomed to them. The present level of taxation in all Western countries, for instance, would have been unthinkable fifty or even twenty years ago. There is a deep truth in Albert Einstein's observation that if there were beings who were flat and without thickness and who lived on the surface of a sphere, they would have no idea of a third dimension. Like domesticated animals, people growing up in the Western type of regulated national communities have no real conception any longer of a wilder life. To the reflecting social scientist the adaptability of the human animal to new conditions will never cease to be one of this world's wonders.”

FALLACIES IN INTERPRETATION OF QUECKENSTEDT'S TEST

A. R. TAYLOR
M.A., M.B. Aberd., F.R.C.S.E.
NEUROLOGICAL SURGEON, ROYAL VICTORIA HOSPITAL, BELFAST

IN 1916 Queckenstedt introduced his test for the detection of spinal subarachnoid obstruction. He noted that compression of the jugular veins caused a “congestion of the brain”, and consequent increase in the cerebrospinal-fluid (C.S.F.) pressure. In the presence of an expanding spinal lesion sufficient to block the subarachnoid space, this increase is not transmitted to the spinal canal, and is therefore not reflected in the fluid level of a lumbar manometer. Queckenstedt wrote of congestion of the brain. Had this conception been retained, and not replaced, as it was, by that of increased intraventricular pressure, later confusion might have been avoided. As the original test was modified, and combined cisternal and spinal puncture methods were introduced to define the site of obstruction more precisely, inaccuracies in the interpretation of results appeared.

The first refinement was added by Ayer (1921) who, having perfected his technique of cisternal puncture, used it in combination with lumbar puncture to show a rise in cisternal pressure without a coincident lumbar increase as additional evidence of spinal obstruction.

About 1924, at least three workers—Fremont-Smith, Cushing, and Eskuchen—independently described a method of combining ventricular with lumbar puncture to confirm the diagnosis of posterior-fossa obstruction, but here conditions are dissimilar to those in the spinal theca, and the test thereby becomes less reliable.

Further improvements in detail were added. Poppen and Hurxthal (1934) pointed out that before evidence of block is manometrically apparent, the subarachnoid obstruction must develop to a degree in which the area left for fluid circulation is less than the area of cross-section of the spinal-puncture needle. Stookey and Klenke (1928) placed the test on a firmer mathematical and mechanical basis by explaining the delayed rise and the rise maintained after removal of jugular compression. Grant and Cone (1934) applied graduated pressures to the neck by a manometer cuff in steps of 5 and 10 mm. Hg and recorded them, with successive C.S.F.-pressure readings, on a chart. This obviated the individual variants of degree and site of finger compression, and gave comparable records compiled by different observers.

Antoni (1931), at the Copenhagen clinic, modified the combined cisternal and spinal test. He postulated that, as the superior caval venous pressure decreased with the inspiratory expansion of the thoracic cage, and the inferior caval venous pressure increased with the descent of the diaphragm, the cisternal level should fall and the lumbar pressure rise with each inspiration, if a block existed between the needles. Wagner (1947), reporting over 800 double punctures from the same clinic, concluded that the test for “respiratory block” was not reliable, because the communicating vertebral venous system equalised the pressure between the superior and inferior caval systems.

In the “reversed Queckenstedt test” saline is injected into the sacral epidural space, raising the pressure at that level. The absence of a corresponding rise at a higher lumbar site signifies subarachnoid obstruction between the two needles.

As a result of these combined methods, many observers, instead of thinking in terms of venous distension causing increased pressure, thought instead of columns of C.S.F. moving from one part of the cerebrospinal axis to another. For example, Elsberg (1941) said: “The compression of the jugular veins causes a venous congestion within the cranial cavity, and as a result, the expulsion of C.S.F. from

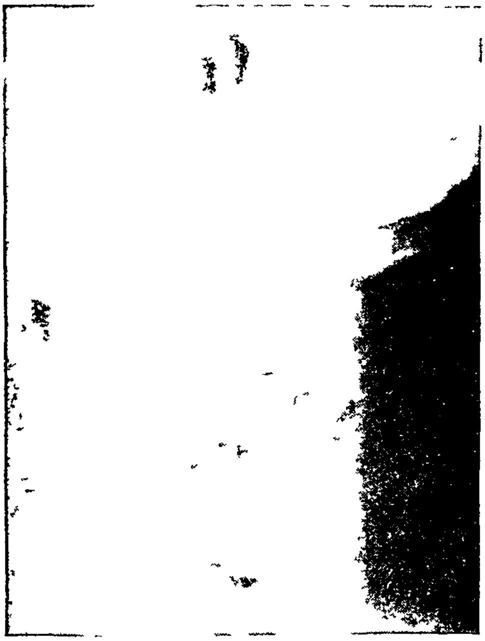

Fig. 1—Injection into the internal jugular vein of a living subject with both jugular veins compressed.

Contrast medium is seen filling the vertebral venous systems of the same side as far as the lower cervical region.

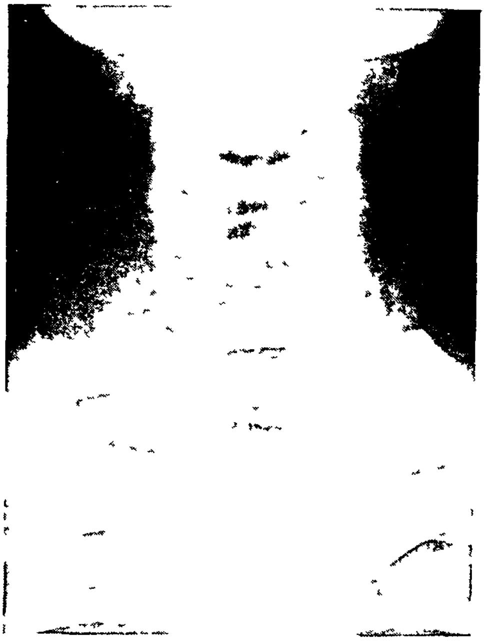

Fig. 2—Injection into the jugular bulb in a cadaver with jugular veins compressed.

The vertebral venous system is filled on both sides to the lower cervical level.

the ventricular cavities." This misconception of rising ventricular pressure was encouraged by Dandy and Blackfan's (1914) theory that the rise in C.S.F. pressure was caused by congestion of the choroid plexuses and increased fluid production in the ventricles. Becht (1920) disproved this by showing that C.S.F. pressure returned to its initial level within 11 seconds after release of jugular compression, but took 6 minutes to return after the volume of C.S.F. was increased by the subarachnoid injection of saline.

That venous and C.S.F. pressures move in parallel was shown by Weed and Flexner (1921) in dogs, the fluid pressure increase bearing an almost constant relationship of 65% to the venous. Bedford (1935) confirmed this. In looking for the explanation of apparent anomalies in the results of Queckenstedt's test, attention must be focused on the changes attending intracranial venous distension as such, rather than those attending a rising C.S.F. pressure in the ventricles, or elsewhere in the cranial cavity.

Evidence for Posterior-fossa Obstruction by Queckenstedt's Test

After the introduction of ventricular puncture, some workers—e.g., Gardner (1928) and Smyth and Henderson (1938)—sought to show that, on jugular compression, pressure rose higher in the ventricle than in the spinal canal if there was obstruction in the posterior fossa.

O'Connell (1943) drew attention to the fact that rise in pressure, measured through a wide-bore ventricular needle was much more rapid than through a narrow-gauge spinal needle, and that pressure rises in manometers connected to ventricular and spinal needles should not be directly compared.

To eliminate this error, recordings were made of a series of combined ventricular and lumbar punctures, using a blunt fine-bore ventricular needle of the same gauge as the lumbar one. Jugular, thoracic, and abdominal compression were successively performed, and manometer readings were recorded in the ventricle and spinal theca. The series observed included some patients with normal intracranial pressure, and others with proven obstruction at the tentorium and aqueduct, or at the foramen magnum. In none of these did the ventricular pressure rise higher or more rapidly than the lumbar pressure. There was apparently some mechanism whereby pressure was equalised throughout the cerebrospinal axis even when the pathways were obstructed. That this mechanism resides in the vertebral venous system is seen at surgical exposure of the posterior fossa.

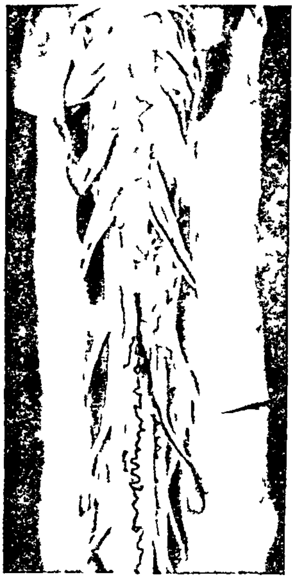

Fig. 3—Spinal canal in the injected cadaver filled with dye to C7.

When jugular pressure is applied, there is a rapid outflow of C.S.F. from the fourth ventricle, and the cerebellum is displaced downwards, but, in addition, there is distension of the whole venous bed in the posterior fossa and in the visible upper region of the cervical spinal canal. Plainly, therefore, a rise in pressure caused by distending this venous bed will be transmitted to the C.S.F. pathways whether there is obstruction at the tentorium and fourth ventricle or not. Outflow of C.S.F. from the fourth ventricle may be impeded, but displacement of venous blood into the cerebellar and spinal veins will not. Obstruction in the posterior fossa may sometimes

Fig 4—Injection into jugular vein of a rhesus monkey with all jugular veins tied off

Dye fills the vertebral venous system and escapes to the innominate veins at the lower cervical level

Fig 5—The monkey's spinal cord, showing the level of venous filling

delay the rise of fluid in a spinal manometer on jugular compression, but it will not prevent it.

Obstruction in the Cervical Canal

A negative Queckenstedt test in the presence of obstruction in the cervical C.S.F. pathways is less easily understood, but has often been described

Symonds and Meadows (1937) analysed seven cases of tumour at and below the foramen magnum. In none was a complete manometric block demonstrated, although in four the rise or fall was described as being a little delayed. In the one case in which a satisfactory myelogram was obtained, complete spinal block was demonstrated. These workers were led to conclude that "the degree of subarachnoid block, in relation to the severity of the clinical symptoms, would appear to be less in these cases of high cervical tumour than it is at a lower level" It is more likely that the degree of subarachnoid block is as great, but the methods of detecting it are subject to error

Martin and Kleyntjens (1950) described three lumbar punctures performed on cases of meningioma at the foramen magnum. Two showed a slow rise and fall of pressure, and one had normal responses to jugular compression. They said "Queckenstedt's test shows little, a complete block being quite exceptional"

Weinstein and Wechsler (1940) described a dermoid tumour in the foramen magnum in which the Queckenstedt responses were normal Congenital deformities in this region may also cause spinal obstruction Gustafson and Oldberg (1940) described four lumbar punctures in their series, two partially blocked and two without evidence of block.

List (1941) recorded five cases of platybasia, four partially blocked and one quite free as judged by spinal manometry In the last case the spinal cord was reduced by pressure to a fibrous-looking band of small calibre

I have observed seven cases of neurinoma or meningioma between C1 and C4 in which subarachnoid obstruction appeared to be complete at myelography or operation, although Queckenstedt's test was negative

Experimental Evidence

It seemed likely that, as in the posterior fossa, the obstruction was being bypassed by transmission of increased venous pressure through the vertebral plexuses Evidence in favour of this hypothesis was collected from venous-injection studies in man and animals

A catheter was inserted into the internal jugular vein of patients undergoing carotid angiography With both jugular veins occluded on the cardiac side of the catheter, injections of contrast material were made. Fig 1 shows the intracranial venous distension spreading into the internal and external vertebral venous plexuses as low as C6–7 Injections of barium and dye into the jugular veins of cadavers cephalad to the point of venous obstruction confirmed this X-rays showed a similar filling of the vertebral venous system (fig 2), and the spinal canal was shown to be filled with dye as far as C7 (fig 3)

Similar injections were made in monkeys after tying all the jugular veins X-rays showed the filling of the vertebral veins and the escape back to the innominate veins and the heart (fig 4) The cord and dura preparation shows that the vertebral venous plexus filling extended, as in the human subjects, to the level of the lower cervical spinal canal (fig 5)

Provided, therefore, that a cervical spinal tumour does not obstruct the extradural as well as the intradural spinal veins, jugular compression will cause distension of the vertebral venous plexus as low as C6–7, with compression of the theca below the obstruction and a rise in pressure at the lumbar manometer This rise may not be as great as that normally produced by this distension plus the C.S.F. displaced from within the skull to the spinal canal and thence to the manometer, but it may be sufficient to deceive even an experienced observer (And in the event,

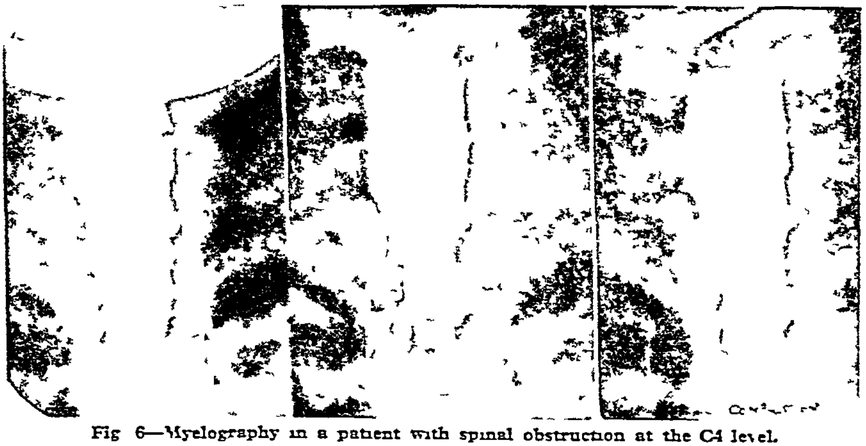

Fig 6—Myelography in a patient with spinal obstruction at the C4 level.

Compression of the jugular veins causes distension of the extradural veins, which narrows the spinal dural canal and causes the oil column to move cephalad.

most lumbar punctures are delegated to the inexperienced) This conception is very important for the understanding of C S F mechanics, because many theories about spinal pressures in Queckenstedt's test have been based on the elasticity or otherwise of the dura, which was presumed to be expanded by the increase of C S F, volume within If the theca is compressed from without in the presence of cervical spinal obstruction, it clearly does not matter whether the dura possesses elastic properties or not If pressure changes are transmitted past a spinal obstruction by extradural venous distension, myelography in such a case should show the oil column narrowing and moving cephalad on jugular compression Fig 6 shows that this does in fact occur

Discussion

The elaborations of Queckenstedt's test by combined puncture methods led to attention being concentrated on changing C S F pressures rather than changing venous pressures The realisation that C S F and venous pressures move in parallel did not help, because observers came to think in terms of increased ventricular pressure being transmitted via the aqueduct to the cisterna magna and the spinal canal in one continuous wave, with obstruction at any point halting the wave As a result, it has been suggested at different times that Queckenstedt's test could help in the diagnosis of aqueduct stenosis, acoustic neurinoma, foramen-magnum tumour, or obstruction of a ventriculocisternal (Torkildsen's) tube The above experiments have shown that it will do none of these things Nor is it a reliable test for cervical spinal obstruction above the level C5–6, unless the extradural as well as the intradural vertebral veins are completely obstructed by the agent compressing the spinal cord A negative Queckenstedt's test should not, therefore, be allowed to cloud clinical judgment in patients showing evidence of cervical spinal-cord compression above this level

Summary

The modifications of Queckenstedt's test are reviewed

Combined cisternal and spinal puncture methods tended to obscure the importance of venous distension as the primary cause of rising cerebrospinal-fluid pressures, as indicated by manometers

Clinical and experimental evidence shows that Queckenstedt's test is unreliable in detecting obstruction of the cerebrospinal-fluid pathways above the C6 level

Acknowledgment is made to Dr W H T Shepherd, of the Royal Victoria Hospital, Belfast, and to Dr Robert Saffley, of the Bangour Hospital, Edinburgh, for their help with the X-ray studies, to the department of microbiology of the Queen s University of Belfast, where the animal experiments were done, and to Mr R G Wood for the photographs

ANTICONVULSANTS AS A FACTOR IN MEGALOBLASTIC ANÆMIA IN PREGNANCY

P B B GATENBY
M D Dubl, F R C P I, M R C P
VISITING PHYSICIAN, ROTUNDA HOSPITAL, DUBLIN,
PHYSICIAN, MEATH AND DR STEEVENS' HOSPITALS, DUBLIN,
PROFESSOR OF CLINICAL MEDICINE, TRINITY COLLEGE, DUBLIN

THERE have been many reports of megaloblastic anæmia induced by anticonvulsant drugs—an association first described by Badenoch in 1954 The relevant literature is well summarised by Hawkins and Meynell (1958) This anæmia has followed the administration of phenobarbitone and phenytoin, and also primidone In 1956, Girdwood and Lenman drew attention to the similarity in chemical structure between folic acid and these compounds They suggested that these drugs interfered with folic-acid metabolism This was confirmed to some extent by Chanarin et al (1958) who studied a patient in whom megaloblastic anæmia developed after primidone therapy They found that both the absorption and storage of folic acid in the tissues were normal and concluded that interference with tissue metabolism rather than deficiency of folic acid was the cause of the anæmia Recently a similar condition was described in a case treated with phenobarbitone (Chanarin et al 1960) Hawkins and Meynell (1958) investigated the incidence of macrocytic anæmia in large numbers of epileptics who were being maintained with these drugs, and found that this complication was rare Macrocytosis was common, however, in these patients, and 45% of those receiving phenobarbitone and phenytoin showed this feature This macrocytosis could be corrected with folic acid

Megabloblastic anæmia in pregnancy is now being recognised more often, and many reports have been analysed by Chanarin et al (1959) In the same paper, these workers produced evidence of a folic-acid deficiency in two-thirds of those nearing the end of their pregnancy, and in all patients with twin pregnancy All pregnant patients with megaloblastic anæmia were found to have a still greater deficiency of folic acid

Consideration of all these reports suggests that megaloblastic anæmia is more likely to develop when anticonvulsants are used in pregnancy Possible interference with folic-acid metabolism by these drugs is likely to increase the effect of the relative folic-acid deficiency which may occur in pregnancy Though Dimsdale (1959) drew attention to the danger of drug-induced megaloblastic anæmia in epileptics during pregnancy, no report of this complication has yet been found

In a recent survey of 100 cases of megaloblastic anæmia in pregnancy seen at the Rotunda Hospital (Gatenby and Lillie 1960), it was noted that 3 of the cases were epileptics receiving anticonvulsants The incidence of epilepsy in the general attendance at this hospital is approximately 1 in 400, so that the incidence of 3%

TABLE I—ANTICONVULSANTS AND MEGALOBLASTIC ANÆMIA IN PREGNANCY

Anticonvulsant drugs	Number of patients	Number of pregnancies	Incidence of megaloblastic anæmia
Phenobarbitone	28	48	0
Phenobarbitone and phenytoin	7	7	4*
Phenobarbitone and primidone	1	1	0
Methoin (Mesontoin)	1	1	0
No treatment	7	13	1
Total	44	70	5

* 1 unconfirmed

gst the cases of megaloblastic anæmia suggested a ual relationship

The records of all pregnancies in epileptics over a six- period (1953 to 1958 inclusive) were studied 70 ces occurred in 44 epileptics In 7 of them (13) no anticonvulsants were being adminis- , because there had been no attacks for many years case of megaloblastic anæmia occurred in this group The remaining cases were divided into groups depending on the anticonvulsants used Table I shows the relative incidence of megaloblastic anæmia There were no cases in 48 pregnancies treated with phenobarbitone alone There were 4 cases (1 unconfirmed by bone-marrow biopsy) out of 7 treated with phenobarbitone combined with phenytoin

In table II details are shown of the established cases All had severe megaloblastic anæmia which responded briskly to folic acid by mouth, 20 mg daily, in spite of continuation of the anticonvulsant treatment Case C is noteworthy because phenobarbitone alone had been administered in previous pregnancies without the development of megaloblastic anæmia None of these cases had achlorhydria Cases A and B are still under observation and neither has shown radiological evidence of gastrointestinal abnormality

TABLE II—MEGALOBLASTIC ANÆMIA IN PREGNANT EPILEPTICS RECEIVING PHENYTOIN

Case	Pregnancy	1st Hb estimation	Onset of anæmia	Hb at onset	Reticulocyte-peak with folic acid
A	2nd (no treatment during 1st)	11·1 g per 100 ml. at 24th week	6 weeks antepartum	5·8 g per 100 ml.	12% on 5th day
B	1st	8·1 g per 100 ml. at 32nd week	4 weeks antepartum	4·3 g per 100 ml	14% on 6th day
C	6th (phenobarbitone during previous pregnancies)	12·4 g per 100 ml at 24th week	2 days antepartum	6·4 g per 100 ml.	15% on 6th day

Summary and Conclusions

From this analysis, it appears that there is a high incidence (3 out of 7) of severe megaloblastic anæmia when phenytoin together with phenobarbitone is used in the treatment of epilepsy in pregnancy It is recommended that, if phenytoin is being administered to an epileptic during pregnancy, either oral folic-acid supplements should be given during the last trimester, or frequent hæmoglobin estimations should be done to detect the onset of anæmia If it proves to be megaloblastic, it will respond well to folic acid, the anticonvulsant treatment need not be interrupted.

The incidence of megaloblastic anæmia in 57 pregnancies in epileptics receiving anticonvulsant therapy was studied retrospectively There were no cases in 48 pregnancies where phenobarbitone alone was used In 7 pregnancies where phenytoin was used as well as phenobarbitone there were 4 cases (1 unconfirmed) of severe megaloblastic anæmia Folic acid cured the anæmia in these cases, while allowing the anticonvulsant therapy to be continued

I wish to thank Dr E W L Thompson, ex-Master of the Rotunda Hospital, for permission to publish this report of patients who were under his care I am greatly indebted to Dr H. C Moore, pathologist, for his assistance.

HYPONATRÆMIA is associated with reduced osmotic activity in the extracellular fluid and may occur with lowered, normal, or increased body-sodium stores It may follow sodium depletion, water retention, or reduction in cellular osmolarity (Schroeder 1949, Sims et al 1950, Rapoport et al 1951, Danowski et al 1955) Renal handling of sodium is variable, and retention or abnormal urinary loss may occur (Rapoport et al 1951, Schwartz et al 1957, Orloff et al 1959)

Hyponatræmia may be found in adrenal failure and severe cardiac, renal, or hepatic disease It has been described in tuberculosis, cerebral disease, and diabetes, and after excessive loss of body secretions by any route (Danowski et al. 1955, Elkinton 1956)

It may develop during acute lobar pneumonia and tuberculosis (Atchley et al 1923, Winkler and Crankshaw 1938, Sims et al 1950) A patient with bronchial carcinoma who showed hyponatræmia and abnormal renal chloride loss was described by Winkler and Crankshaw (1938) Recently, Schwartz et al (1957) reported two patients with carcinoma of the bronchus in whom hyponatræmia and renal sodium loss probably resulted from inappropriate secretion of antidiuretic hormone We describe here a further patient with a bronchial neoplasm and hyponatræmia in whom this mechanism did not operate As well as deficient sodium retention, he had aminoaciduria and increased phosphate excretion The presence of an acquired renal tubular defect is suggested

Case-record

A stoker, aged 53, was admitted to the Gordon Hospital on April 17, 1959 For two months he had suffered malaise, non-productive cough, and loss of appetite, with particular revulsion for sweet and starchy food. He had lost 17 lb, and in the previous fortnight had suffered from nausea, with vomiting on four occasions During the same period he had noted cramps in the abdomen and legs

He had had a dry mouth and increased thirst for a week before admission On April 15, he had fainted, and had since been confined to bed There was no disturbance of micturition, but he had been constipated for a fortnight He had been a moderate pipe smoker for years, and took little alcohol

Examination

He was thin and wasted There was no clinical dehydration or œdema No abnormal pigmentation was noted B P 100/60 mm Hg Respiratory system fine râles at bases of both lungs, otherwise normal The tongue was furred, but the mouth was not dry

Investigations

Daily serum-electrolyte and blood-urea levels, urine-volumes and electrolyte content, and fluid and sodium intakes are shown in table I and in figure

Blood—Hæmoglobin 15 0 g per 100 ml Erythrocyte-sedimentation rate (Wintrobe) 11 mm in the first hour Total white-cell count 9000 per c mm (neutrophils 70%, lymphocytes 30%) Liver-function tests, serum-amylase, and serum-cholesterol normal Serum-albumin 3 9 g per 100 ml Serum-globulin 2 5 g per 100 ml Random blood-sugar 123 mg per 100 ml Wassermann and Kahn tests negative Serum-alkali reserve (day 13) 24 mEq per litre Serum-alkaline phosphatase 7 King-Armstrong units Serum-calcium 10 6 mg per 100 ml , serum-inorganic phosphate 2 2 mg P per 100 ml (day 2) Serum-calcium 13 3 mg per 100 ml , serum-inorganic phosphate 1 6 mg P per 100 ml (day 14) Serum-creatinine 0 6 mg per 100 ml (day 14)

Urine—Urinary calcium 350 mg per 24 hours Urinary phosphate 480 mg P per 24 hours Urinary creatinine 450 mg per 24 hours (day 14) Urinary aldosterone excretion (Dr R V Brooks) 1 8 µg per day (day 16), 1 7 µg per day (day 17) (normal range 3–8 µg per day with a mean of 5 µg) Steroid excretion is shown in table II

The specific gravity was always within the range 1 010–1 026 No albuminuria Intermittent glycosuria and ketonuria There was no glycosuria after day 13, and no ketonuria after day 18 Paper chromatography of urine for aminoacids (Dr J H Wilkinson) showed (1) a large increase of alanine, glycine, glutamine, histidine, lysine, threonine, and γ-amino butyric acid, (2) a moderate increase of glutamic acid, taurine, and serine, (3) small quantities of valine, leucine, and tyrosine, and (4) traces of methyl histidine and cystine This pattern of generalised aminoaciduria was present up to the time of death

Sputum—No malignant cells

X-ray of chest—Mass in left lung near hilum, with bilateral hilar-gland enlargement Normal pulsation and diaphragmatic movement on fluoroscopy

Isotope studies (Dr J F Zilva, Dr J P Nicholson)—Total exchangeable sodium (day 12) 2510 mEq = 51 1 mEq per kg (normal range 37–56 mEq per kg) Total exchangeable potassium (day 12) 2530 mEq =51 1 mEq per kg (normal range 37 5–61 mEq per kg) Na/K=1 00 (normal range 0 69–0 95) Bromide-space (day 13) 15 9 litres=340 ml per kg , (day 14) 16 3 litres=359 ml per kg (normal range for his build 248–378 ml per kg)

Electrocardiography—Day 1, alternating atrial flutter and fibrillation Fast ventricular rate of about 150 beats per minute with both rhythms Day 5, sinus rhythm, rate 80 beats per minute Tracings otherwise normal

Progress

The history of recent cough and the X-ray findings suggested bronchial carcinoma Severe hyponatræmia (109 mEq per litre) was found on admission and was associated with abnormal renal sodium loss (79 mEq in second half of day 1)

He gradually became worse He was moderately thirsty but too ill to drink unless assisted During the first four days he took sweetened fruit drinks only, and he continued to refuse food throughout the rest of his illness

Adrenal failure caused by bilateral metastatic deposits seemed unlikely with a normal blood-urea, a low serum-potassium (3 4 mEq per litre, day 1), and no pigmentation His blood pressure (95–100/60 mm Hg) was low but this was due to tachycardia, and it rose on day 4 to 120/80, when the arrhythmia reverted to sinus rhythm, though the hyponatræmia persisted (107 mEq per litre) He was so ill that it seemed best to give extra salt and sodium-retaining hormones until more was known of his adrenal function On day 5, oral salt in cachets and intravenous saline were begun (table I and figure), and he was encouraged to drink more He cooperated readily and high intakes were achieved between days 6 and 11 He also took a total of 6 mg fludrocortisone between days 5 and 9 This potent salt-retainer was used to avoid confusion in estimations of urinary steroid excretion which were done at this time Fludrocortisone was stopped as soon as these results were known

With this therapy there was slight improvement, though he remained weak The serum-sodium rose only slowly, and continued to rise when fludrocortisone was discontinued on day 8 and sodium intake was increased Intensive sodium therapy was given up to day 11 by which time the serum-sodium level had risen only to 121 mEq per litre

Between days 12 and 16, water intake was reduced as much as possible to see if this would affect the renal sodium loss as in the cases of Schwartz et al (1957) Sodium supplements were continued, so that he also received 1140 ml fluid daily intravenously, and negative fluid balance was not, therefore, achieved In this period, with an intake of 228 mEq sodium daily, the serum-sodium level continued its slow rise to 132 mEq per litre From about day 12, his condition steadily worsened, with increasing back pain at the level of the lower part of the thoracic spine, and by day 17 he was very ill No more intravenous saline was given, but oral supplements were continued for another 2 days His fluid intake was about

1·5 litres daily. He became emaciated, and bronchopneumonia developed. Finally he lapsed into coma and became clinically dehydrated. There was a terminal rise in blood-urea levels, and the serum-sodium rose to a maximum of 142 mEq. per litre on day 20, though it fell again the following day to 127 mEq. He died on day 22.

Necropsy

At necropsy (Dr. J. S. Cornes) an oat-celled anaplastic carcinoma was discovered, originating in the lingular bronchus, and spreading to the lung, mediastinum, and left supraclavicular lymph-nodes. No other macroscopic spread was found, but histological examination showed infiltration of the liver and spleen by tumour cells.

The kidneys were macroscopically and histologically normal. Histochemical staining (Dr. John Pryse-Davies) showed normal alkaline phosphatase, acid phosphatase, non-specific esterase, succinic dehydrogenase, and lactic dehydrogenase activity. Microdissection (Dr. E. M. Darmady) revealed no abnormality.

The adrenals were enlarged (combined weight 22 g.) and histologically showed widening of the cortex principally in the zona fasciculata. Histochemical staining (Dr. Pryse-Davies) for alkaline phosphatase, acid phosphatase, non-specific esterase, succinic dehydrogenase, and steroid 3-β-ol dehydrogenase suggested a hyperactive adrenal gland with increased steroid metabolism.

The parathyroids showed slight uniform enlargement. The pituitary contained a small developmental cyst, 3 mm. in diameter, but otherwise was normal.

TABLE II—URINARY STEROID EXCRETION

Day	Urinary steroids (mg. per 24 hours)		Steroid therapy
	17-hydroxy-steroids	17-keto-steroids	
4	17·8	[illegible]	Nil

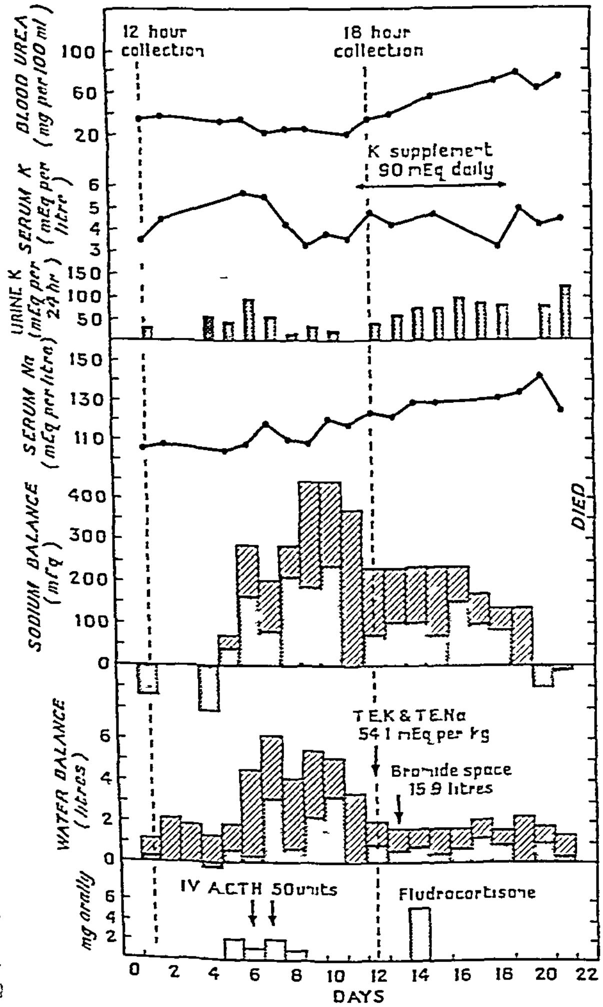
6	66·0	16·8	Fludrocortisone 1 mg. oral Corticotrophin 50 units I.V.*
7	65·0	21·0	Fludrocortisone 2 mg. oral Corticotrophin 50 units I.V.
9	37·0	11·5	Nil
10	2·1	2·0	Nil
20	17·4	7·7	Nil
21	17·7	18·8	Nil

* I.V. = intravenous.



Water and sodium balance calculated from intake and output figures with no allowance for extrarenal loss or water of metabolism.

Daily intake plotted up from baseline. Daily output plotted down from intake figures. Shaded areas above baseline represent positive balance, shaded areas below are negative balance. Intake data only for days, 2, 3, 11, and 19. For potassium, urinary figures only are shown. T.E.K. = total exchangeable potassium. T.E.Na = total exchangeable sodium.

Discussion

The outstanding feature was the extreme hyponatræmia accompanied by malaise, cramps, and thirst. Mechanisms such as decreased cellular osmotic activity or a new steady state, which have been suggested to explain hyponatræmia in severe illness (Sims et al. 1950, Danowski et al. 1955) did not operate in our patient whose hyponatræmia improved as his clinical state deteriorated.

Addison's disease was not present, nor was there any evidence of the usual type of salt-wasting renal disease which is associated with obvious changes in the kidneys (Stanbury and Mahler 1959). The hyponatræmia was clearly associated, however, with deficient renal sodium retention. This is seen on day 1, and on day 4 when 108 mEq. sodium were excreted after at least 4 days without any salt intake. This sodium-leak was partially inhibited by fludrocortisone on day 5, but the presence of more than a trace of urinary sodium at this low serum-level (107 mEq. per litre) suggests that tubular response was impaired. By day 14, a large dose of fludrocortisone had no effect on sodium excretion showing that the tubular defect had increased.

Aldosterone excretion was reduced on days 16 and 17. By then massive sodium repletion had occurred. Extrapolating from the results on day 12 (allowing 10 mEq. daily for extrarenal loss), total exchangeable sodium is estimated at 2866 mEq. for day 16 (approximately 61 mEq. per kg.) and his serum-sodium had risen to a reasonable level for his clinical state. The low aldosterone excretion at this stage is therefore not surprising.

An estimate of the metabolic state on admission may be made from the isotope studies.

On day 13 the bromide-space was 15·9 litres (within normal limits), and before this marked positive water balance had occurred. Allowing 700 ml. daily as the balance between insensible loss and water of metabolism, a positive balance of 6·2 litres occurred between days 7 and 11. Unfortunately, the urine on day 11 was lost, but the intake makes a negative balance unlikely. Ignoring this day a positive balance of approximately 5·6 litres existed between days 5 and 13. Thus, on day 6, the extracellular fluid volume was estimated at 10·3 litres (about 220 ml. per kg.). This figure would have changed little from the time of his admission, and is abnormally low.

Total exchangeable sodium on day 12 was 2540 mEq. Ignoring day 11 again cumulative sodium retention from day 5 to day 12 was 972 mEq. The amount of food taken was negligible, and allowing 10 mEq per day for extrarenal sodium loss, the estimate for total exchangeable sodium on day 5 was, at most, 1640 mEq (approximately 35 mEq per kg)—an abnormally low figure Total exchangeable potassium on day 12 was 2540 mEq, and cumulative potassium loss in the previous week was 258 mEq (again ignoring day 11) Allowing 10 mEq daily for unmeasured potassium loss, the total exchangeable potassium on day 5 was estimated at about 2868 mEq (approximately 61 mEq per kg), which is in the upper normal range

Thus it appears that our patient on admission was depleted of sodium with a reduced extracellular-fluid space

In their two patients, Schwartz et al (1957) thought that carcinoma in some way caused inappropriate secretion of antidiuretic hormone This produced sodium loss by increased glomerular filtration and, because extracellular volume did not fall, by a failure of aldosterone secretion to rise with sodium depletion Both patients had severe hyponatræmia, in one case as low as 103 mEq per litre, with few symptoms In one the extracellular volume was measured, and was found to be raised

In our patient, the low estimate for extracellular space on admission makes it unlikely that inappropriate secretion of antidiuretic hormone caused his sodium loss The increased thirst in the week preceding admission is in keeping with this view, though thirst can occur with an increase in body water (Wynn and Rob 1954)

The effect of water restriction (days 12–16) was unimpressive There was no dramatic reduction in urinary sodium loss as in the patients of Schwartz et al (1957) and though restriction of water was not severe, it was more than was needed in one of their cases to reverse sodium loss Administration of large amounts of fluid caused improvement, rather than deterioration, and sodium given in this phase was largely retained in contrast to the results in their patients The poor response to salt-retaining hormones is a further point of distinction, and in addition our patient probably produced hypotonic urine on some days (e g, day 8, table I) when specific gravity was not recorded, whereas in the cases of Schwartz et al (1957) urine was hypertonic to plasma

In our patient, it seems that the renal sodium leak was due to impaired tubular function With liberal intakes, sodium loss was not excessive, and repletion was easily achieved However, when sodium intake was low, an obligatory renal salt-loss was revealed, leading to sodium depletion and, eventually, hyponatræmia

This defective reabsorption of sodium, together with intermittent ketonuria and glycosuria, suggested proximal tubular damage, and investigation led to the unusual finding of generalised aminoaciduria Other recognised causes of renal aminoaciduria were absent, and there was no evidence of the adult Fanconi syndrome (Wallis and Engle 1957) in which sodium loss, in particular, does not occur Overflow aminoaciduria may be found with increased protein breakdown, and since the plasma-aminoacid level was not estimated, this is a possibility in our patient, though other features favour its renal origin

Impaired phosphate reabsorption and low serum-phosphate levels accompanied the aminoaciduria, providing further evidence of proximal tubular damage The terminal hypercalcæmia and necropsy findings of parathyroid gland enlargement were probably due to secondary hyperparathyroidism

The distal tubular exchange mechanism of potassium for sodium could function normally as shown by falling sodium excretion in the last week, with increased potassium excretion and K/Na ratios, particularly evident on day 21 24-hour creatinine-clearance on day 14 was reduced, and rising blood-urea levels were recorded in the last week, indicating progressive reduction in glomerular filtration This might have reduced the load on the proximal tubules to a level at which they could function competently The resultant fall in distal tubular flow might then allow the efficient cation exchange and sodium conservation seen on day 21 A diminution in proximal tubular load would also explain the disappearance of glycosuria and ketonuria in the week before death

A defect in proximal tubular function was therefore thought to be present, and a similar defect was postulated by Rapoport et al (1957) as the cause of hyponatræmia in their patients with tuberculous meningitis However it remains difficult to explain the urinary composition on days 1 and 4 The metabolic state on admission should have resulted in maximal aldosterone secretion The modest potassium excretion and low urinary K/Na ratio at this time is surprising and, with the poor response to administered steroids, suggests that distal tubular function was also impaired

Summary

Severe hyponatræmia developed in a man of 53 with bronchial carcinoma He showed poor renal sodium conservation which, with negligible intake because of anorexia, had caused sodium depletion

Repletion was easily achieved and fluid restriction did not affect the sodium loss Metabolic studies suggested that, on admission, he was depleted of sodium, with a reduced extracellular-fluid volume

There was no evidence of adrenal failure, and at necropsy the adrenal glands were enlarged and showed signs of hyperactivity

The renal response to fludrocortisone and corticotrophin was poor There was no clinical evidence of any of the usual types of salt-wasting renal disease, and at necropsy the kidneys were normal on detailed histological examination

There was evidence of functional damage to the proximal tubules with generalised aminoaciduria, glycosuria, ketonuria, and increased phosphate excretion Aminoaciduria was constant throughout, but glycosuria and ketonuria were intermittent and disappeared in the last week

The distal tubular exchange of sodium for potassium was active terminally, though perhaps not on admission It is suggested that the sodium loss was mainly due to proximal tubular damage, and that the bronchial carcinoma had caused this unusual derangement of tubular function

We wish to thank Dr R D Tonkin, under whose care this patient was admitted, for permission to report this case, and Dr R I S Bayliss for advice on the manuscript The microdissection of the kidneys was carried out by Dr E M Darmady The urinary amino-acid determinations were performed by Dr J H Wilkinson We are indebted to Dr R V Brooks for the urinary aldosterone assays Details of the adrenal and renal histochemical studies were kindly provided by Dr John Pryse-Davies The results of the isotope studies were provided by Dr J F Zilva and Dr J P Nicholson The necropsy was performed by Dr J S Cornes The figure was prepared by the department of medical illustration, Guy's Hospital

POSTPARTUM PRE-ECLAMPSIA

I R McFADYEN
M B Glasg
FLIGHT LIEUTENANT, R A F
From the Royal Air Force Hospital, Aden

A WOMAN, aged 19, had an eclamptic fit fifteen hours after she had her first baby She had given no evidence of pre-eclamptic toxæmia while pregnant, or during her eight-hour labour An episiotomy was necessary for delivery, and, in the course of its repair, she seemed drowsier than would have been expected from the 100 mg pethidine and the gas-and-air analgesia she had received during labour That night she slept uneasily, complaining of epigastric discomfort, and at 6 A M next day her blood-pressure (B P) was 140/90 mm Hg an hour later she had the fit

The patient was first seen during the sixteenth week of pregnancy No history of serious illness, previous pregnancy, or fits was given (this was confirmed in the puerperium) Her general condition was excellent Hæmoglobin 87% (Haldane), blood-group B, rhesus-positive, Kahn-negative The B P was 130/70, weight 105 lb , and her urine showed no abnormality Thirteen visits were made during the pregnancy Apart from a trace of albumin in a morning specimen of urine at the thirty-seventh week, and slight swelling of the ankles the week before that, the only abnormality of the pregnancy was a degree of hydramnios at the thirtieth week sufficient to warrant an X-ray of the abdomen The hydramnios decreased slowly but was still present at term The weight rose gradually to 128 lb at term, and fell 1 lb in the following week The blood-pressure remained between 110/60 and 120/80 during the pregnancy

Progress

Day 1 —A healthy 6½ lb infant, born ten days after the estimated delivery date The labour was uneventful Total blood loss 8 oz , 0 5 mg of ergometrine was given intramuscularly after delivery of the placenta

Day 2 —B P after the fit, 140/90 There was no residual paralysis, but facial œdema was noted and this increased during the next few hours The patient was sedated with barbiturates, and given a low-salt diet During the day her B P remained at about 130/90 Morphine was given that night as she complained of headache

Day 3 —The B P fell until it was 125/80 in the evening, the œdema subsided, and the patient had no complaints

Day 4 —About seventy-two hours after delivery the frontal headache and facial œdema returned The breasts became engorged and treatment for the suppression of lactation was begun Her temperature rose until it was 102 6°F by the evening She was moved into an air-conditioned room, and sedated with 6 g amylobarbitone six-hourly and 25 mg chlorpromazine orally twice daily The hæmoglobin was 88% (Haldane) and the hæmotocrit value 40%

Day 5 —A morning catheter specimen of urine contained 200 mg albumin per 100 ml , 15–25 red blood corpuscles, and 3–4 white corpuscles per high power-field, it was sterile A Foley catheter was introduced and nitrofurantoin 100 mg given six-hourly to prevent a urinary infection She passed 1290 ml of urine that day The œdema and headaches remained The temperature fell to 98 4° by the evening The blood-pressure, however, started to rise during the day

Day 6 —The B P continued to rise until in the evening it reached 170/100 At that point 12 5 mg hydrallazine was given orally this was followed an hour later by a fall in B P to 145/100 The dose was increased by stages to 37 5 mg four-hourly The B P fell gradually, until on the tenth day it was consistently 130/80 at the time that the next dose was due

The typical pre-eclamptic facies and headache remained until the sixth day when, along with the albuminuria, they started to subside On the ninth day the catheter was withdrawn, the administration of chlorpromazine was stopped, and the patient was moved out of the air-conditioned room The output of urine did not fall below 950 ml per twenty-four hours, nor did the blood-urea rise above 20 mg per 100 ml and the blood-electrolytes remained within normal limits

The hydrallazine was continued until the fifteenth puerperal day It was gradually reduced thereafter, and was stopped on the twentieth day The B P had then been 105/75 for three days, there was an occasional trace of albuminuria, and the patient had no symptoms The baby was bottle-fed and thriving

Six weeks after delivery the patient was seen at the postnatal clinic She had suffered no headaches or swelling of the ankles since leaving the hospital, nor were there any other complaints The urine contained no albumin, the B P was 110/75, and she weighed 106 lb Uterine involution was satisfactory

Discussion

Stander et al (1946) described 21 cases of eclampsia occurring within thirty hours of delivery 13 of these had shown no evidence of antepartum pre-eclamptic toxæmia In 9 cases of postpartum convulsions in the first twenty-four hours of the puerperium published by Hofmeister and Brown (1953), 2 had given no previous signs of pre-eclampsia Theobald (1955) quotes 4 cases of antenatal eclampsia in patients known to have been normal at some time in the twenty-four hours before the fits It is clear that this fulminating eclampsia can also occur in the puerperium It is not, however, common for a patient to develop the pre-eclamptic syndrome for the first time after delivery and after a fit, in none of these series is it mentioned Hamilton (1953) states that hypertension and convulsions may be produced by intravenous ergometrine given at the time of delivery, but this is not accompanied by œdema and albuminuria, and the blood-pressure usually settles within four hours

There is a school of thought which holds that pre-eclamptic toxæmia and eclampsia are due to increased myometrial tension, pointing out that twins and hydatidiform moles are examples of an overdistended uterus being frequently associated with pre-eclampsia Theobald (1955) gives as one of his essential criteria for any hypothesis purporting to explain the genesis of eclampsia that it must afford a reasonable explanation of eclampsia occurring up to four days after delivery of the placenta, and many find this a stumbling-block in accepting this hypothesis

A possible explanation of my case can be obtained from the concept of pregnancy as "a kind of physiological Cushing's syndrome" propounded by J S L Browne and elaborated by F J Browne (1958) In this it is held that the adrenal cortex undergoes hyperplasia in pregnancy under the influence of the large quantities of corticotrophin produced by the hypertrophied anterior pituitary and the placenta, and Poideven's (1959) demonstration of the relationship of striæ gravidarum to adrenal cortical hyperfunction supports it The excess of corticosteroids produced has been demonstrated by Gemzell (1953) who

found that in the last three months of normal pregnancy the blood level of 17-hydroxycorticosteroids is four times the normal non-pregnant value. This would produce œdema and hypertension were it not that the healthy placenta inactivates the excess of pressor substance. If, however, placental function is diminished below some critical value by placental ischæmia (as may occur in essential hypertension, in a primigravid uterus which has hypoplastic vessels, or in twin pregnancy) pre-eclampsia develops. The same investigator has also shown that immediately after delivery the corticosteroid level is seven times the normal, but that it falls to the non-pregnant level by the sixth puerperal day. It might be expected that this would produce hypertension as the placenta is no longer present. This, in fact, happens. Browne (1958) quotes findings, in Sydney and London, that 20–30% of women whose blood-pressure remains within normal limits throughout pregnancy and labour are hypertensive in the first three days after delivery.

I have recently seen two patients in whom the pre-eclamptic syndrome developed after normal pregnancies; a third patient developed hypertension after a forceps delivery, during which she received two doses of 0·5 mg. ergometrine each.

Case 1.—A patient, whose first pregnancy and puerperium were quite uneventful, delivered her second child after a three and a half hour labour at term, and was given 0·5 mg. ergometrine intramuscularly. Antenatally her B.P. had not risen above 125/75, nor was there any other abnormality. One and a half hours after delivery she vomited and complained of headache. Her B.P. was then 180/110. She was sedated with morphine. Six hours later the headache was still present and she had developed generalised œdema with typical pre-eclamptic facies. The B.P. was 155/100, and a swab specimen of urine contained albumin ++. Sedation was continued and the œdema gradually settled. Thirty-six hours after delivery the headache and œdema had disappeared, the B.P. was 135/85, but there was still albuminuria. Thereafter the puerperium continued normally. The patient was discharged on the tenth puerperal day, her B.P. being 130/80, and the urine contained a trace of albumin.

Case 2.—Normal labour after a second uneventful pregnancy. A single intramuscular dose of ergometrine was given after delivery. On the third day of the puerperium the patient developed headache, hypertension (155/100) and gross generalised œdema. These increased in severity on the fourth day and then responded to rest in bed, sedation, and chlorothiazide therapy. She left hospital on the twelfth day, but the œdema recurred when she was at home and did not disappear for some weeks. The patient was a midwife, and remembered a similar sequence of events after her first confinement.

Case 3.—A primigravida with an uneventful antenatal course, the highest B.P. reading being 130/65. After a twenty-five hour labour she was delivered with forceps under pudendal block anæsthesia, because of second-stage delay. Ergometrine 0·5 mg. was given with delivery of the anterior shoulder. As the uterus tended to relax an intramuscular dose of 0·5 mg. ergometrine was given. One hour and fifty minutes after delivery she complained of nausea; the B.P. was then 170/105. The patient was sedated with amylobarbitone. The B.P. fell steadily; four hours after delivery it was 135/80, and it did not rise again. There was no œdema.

The development of the pre-eclamptic syndrome after emptying of the uterus in the first two of these cases could easily be interpreted in terms of the foregoing hypothesis. A similar transient hypertension to that occurring in the third case was noted after a cæsarean section where the patient also had a double dose of ergometrine, and it is probable that the rise in blood-pressure was caused by the ergometrine in both cases.

Summary

A case of postpartum pre-eclampsia with one eclamptic fit is described in a patient who had hydramnios but no pre-eclamptic toxæmia before delivery.

A possible explanation is that the already high blood-levels of 17-hydroxycorticosteroids during the last three months of pregnancy rise still more immediately after delivery, and do not fall to normal until the sixth puerperal day. Pre-eclampsia will occur in this period if, through ischæmia, placental function is reduced below some critical value. Postpartum pre-eclampsia may arise once the placenta is delivered, because the excess of pressor substance is then no longer inactivated, and hypertension and œdema result.

I wish to thank Dr. J. B. Hewitt for his encouragement in the preparation of this paper, and the Director General of Medical Services, Royal Air Force, for permission to publish.

Preliminary Communication

HYALINE MEMBRANE FOLLOWING TOTAL BODY RADIATION

RELATION TO LUNG PLASMINOGEN ACTIVATOR

In 1940 Warren and Spencer[1] pointed out that hyaline membrane formation was the most definite of all changes produced in the lung by X-irradiation of the chest. These changes were observed after "chest wall doses" of 800–15,000 r. Though hyaline membrane was by no means pathognomonic of irradiation lung damage, its association with œdema, fibrosis, diminished inflammatory response, and hyalinisation of arterial walls was sufficiently unusual to enable irradiated lung to be distinguished from the non-irradiated. The pathogenesis of this lesion is not understood.[2]

Recently patients with far-advanced malignancies have been subjected to total body radiation (T.B.R.) at the National Naval Medical Center, utilising a dual ^{60}Co irradiator.[3] Clinical results are to be described elsewhere, but we wish to report that at necropsy hyaline membrane and fibrinoid deposits have been prominent in cases surviving at least two weeks after treatment.

Lieberman[4] has recently associated hyaline-membrane disease of children with deficiency of plasminogen activator in the lung. This tissue enzyme converts plasminogen to plasmin, the active fibrinolytic enzyme of the body. Lungs normally contain high levels of plasminogen activator.[4,5] Lieberman reasons that because of the relative insolubility of lung plasminogen activator its action is primarily local. In situations where there may be a pathological deposition of fibrin in the lungs, it would

* Assayed for inhibitor—all positive.

be the activator's function to activate the fibrinolytic system and effect the fibrin's removal. Persistence of fibrin deposits due to a defect in this system would lead to hyaline-membrane formation[4] and fibrosis.

The fibrin-plate technique of Astrup as outlined by Lieberman[4] was utilised and in addition fortified with 0·01 M Ca ions. The latter are added to saturate the citrate of commercial bovine fibrinogen and obviate non-enzymatic lysis of the fibrin.[5] This technique is considered quite sensitive and specific for the detection of plasminogen activator.[7]

OBSERVATIONS

Lieberman[4] has well documented the presence of activator in normal adult lung and this has been confirmed by us in a case of traumatic death. Two men who had undergone T.B.R. therapy were investigated. One had received 450r T.B.R. for disseminated lung cancer 18 days before death, and the other 1500r T.B.R. 15 days before death. The latter had no associated malignancy and had been treated in conjunction with an attempted transplant of kidney. In both instances hyaline membrane was present in the lung. Intensity of membrane formation has generally been associated with high dosage and survival for more than 6–8 weeks after therapy.[2] In both cases the assay of lung tissue failed to demonstrate any plasminogen activator.

To follow the sequence of events eleven dogs were subjected to T.B.R. in similar fashion to the human subjects. The table shows the results of assays of lung activator at various intervals in these eleven dogs and in ten controls.

The absence of activator in the irradiated animals could be due to inhibition. Portions of lungs from three animals with absence of activator were homogenised and the homogenate was mixed with equal volumes of an active lung homogenate. In each case the activity of the normal lung was completely inhibited. The animals tested are indicated in the table by an asterisk.

None of the lung sections showed the classical signs of radiation lung damage, and often they were described as normal. Since several weeks are generally required for the development of hyaline membrane,[2] and the animals in this dose range of T.B.R. seldom survive beyond the second week, this finding might be expected.

COMMENT

In two men treated by total body radiation hyaline membrane was found in the lung. Plasminogen activator was apparently absent.

The enzyme soon disappeared from the lungs of dogs given T.B.R. of 800–1000r, but these showed no morphologic change suggestive of the first stage of either hyaline membrane or fibrosis.

Our findings are consistent with the production in irradiated lung of a potent inhibitor of plasminogen activation.

Further studies are in progress to assess the influence of drugs and radiation technique on the activator system in the lung.

The opinions expressed in this paper are those of the authors and are not necessarily those of the Navy Department.

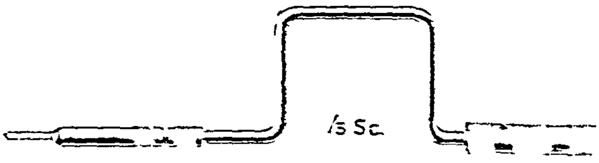
New Inventions

A BRACE SCREWDRIVER

ALTHOUGH Fitzgerald[1] described a brace screwdriver several years ago, this has never become popular, and the ease with which screws can be inserted by its use has not been generally appreciated.

Repeated gripping of a conventional screwdriver and pronating and supinating the forearm, can be very tiring—as many as 150 repetitions of this movement being necessary to insert four screws. The brace screwdriver, by its continuous action, removes this strain and also eliminates the inertia of the screw which develops each time we stop turning. The lessened resistance diminishes the chance of the screw breaking and the brace gives better control.



The type of brace is important. The model here illustrated, adapted from a socket spanner, can be held firmly along the axis of the screw. There should be no sleeve on the crank handle so that the hand can appreciate small changes in resistance during insertion. Some screw-holding attachment is essential. A simple holding sleeve, made by the London Splint Co. for one of their conventional screwdrivers, was used at first and proved quite satisfactory. The Williams screw-holding device, made by Chas. F. Thackray Ltd., although more elaborate, could also be used for this purpose. The brace here illustrated uses the Stryker screw-holding attachment. The Stryker attachment was devised for a power-driven continuously rotating screwdriver, and it is particularly suited to the rotary action of the brace. It has the great advantage over any other screw-holding attachments that the chuck not only releases the screw head automatically but also allows the screw to be fully driven home and tightened by one continuous action, thereby avoiding the need to complete the last few turns with a conventional screwdriver.

This final pattern of brace screwdriver is available from Messrs. Down Bros. Ltd., 21 St. Thomas Street, London S.E.1. By its use screws can be inserted into the upper femur with appreciably greater speed and precision than by any previously available hand-driven device.

Reviews of Books

The Problem of Acute Hypothermia

Editor P M STARKOV Translated from the Russian by R E HAMMOND Editor of English edition E NEIL, M D, professor of physiology, Middlesex Hospital Medical School London Pergamon Press 1960 Pp 329 70*s*

THIS book contains the results of many years research in Professor Starkov's department in Omsk There are twenty-eight articles by the fourteen workers concerned, and they are all physiological, though the hope is expressed that some of the conclusions may be put to practical use The subject titles alone make interesting reading, for, as might be expected, they imply a quite different approach to the physiology of hypothermia from that in the Western world, where much of the work has been planned pragmatically, according to the needs and problems of the operating-theatre, and not so much concern, perhaps, is felt about the basic differences between the body functions at normal temperature and those revealed during hypothermia Physiologists will therefore welcome the results of study on such fundamentals as cold effects on blood-flow in limbs and viscera, on the effects of direct cerebral cooling, and the use in hypothermia investigation of the values accorded by such familiar parameters as those of the heart-lung preparation, decerebrate cat, isolated rat uterus, and skeletal muscle Behaviour and conditioned reflexes in puppies and adult dogs are subjects of natural interest to Russian physiologists, and the response of these nervous patterns to hypothermia is the subject of one of Professor Starkov's own articles

The publishers regret that for speed and economy of production the text is in typescript photolithography, but the quality of the pages is even and good, and the content more than makes up for any deficiency The translation is commendably clear

Lectures on Hæmatology

Editor F J G HAYHOE, M D, M R C P, department of medicine, University of Cambridge London Cambridge University Press 1960 Pp 247 60*s*

THESE lectures were delivered at Cambridge in December, 1959, at a course for physicians and clinical pathologists "having hæmatology as one of their main interests" Four of these lectures will interest any hæmatologist J V Dacie gives some facts from his unique experience in hæmolytic anæmia, W M Davidson provides an excellent account of iron metabolism and treatment, G Wetherley-Mein describes interestingly and practically what is meant by "myeloproliferative syndromes", and R M Hardisty makes a gallant attempt to bring together in a moderately coherent account what we now know about hæmostatic processes The other lectures are good, sometimes very good, reporting work that will be familiar to many hæmatologists R H Girdwood on megaloblastic anæmias, George Discombe on transfusion hazards, and J C White on hæmoglobin variants summarise their already published work Dr Hayhoe himself draws on some pages from his recent book on leukæmia Richard Doll writes on the incidence of leukæmia and the significance of environmental factors, D A G Galton on the chemotherapy of leukæmia, G I C Ingram on congenital and acquired disorders of blood coagulation, and J F Ackroyd on the pathogenesis of purpura H E M Kay brings together a useful summary of published results on attempts to use marrow transplants in the treatment of leukæmia

This sort of book falls between two stools the specialist in hæmatology will be interested only in the first four lectures we mentioned, the more general physician or pathologist with a main interest in hæmatology will hardly wish to buy a set of lectures that will need revision in a short time, especially when he can buy a whole textbook of hæmatology, containing nearly everything in this volume and a lot more, for rather less This volume is to be one of a series why not publish the others in a less expensive form—say, paper back with plastic binding and without some of the illustrations, none of which, in this hæmatology volume, are really necessary?

Chemical Micromethods in Clinical Medicine

R H WILKINSON, M D, assistant chemical pathologist, The Hospital for Sick Children, London Oxford Blackwell Scientific Publications 1960 Pp 121 40*s*

EMPHASIS on micromethods in chemical pathology has increased steadily during the past twenty years It was gradually realised that blood-sugar and blood-urea were not the only substances that could be measured using capillary blood and that it was obviously more considerate and convenient to take small samples of capillary blood by needle-prick than larger ones from a vein by syringe It has also become clear that small amounts of heparinised blood may yield as much plasma as larger amounts of clotted blood can yield serum These considerations apply particularly to pædiatrics, and in this country notable contributions to microchemical methods have come from The Hospital for Sick Children, Great Ormond Street, and some very important ones from the author of this little book There are only about 100 pages of text, of which 10 are taken up by illustrations, not all of them essential (a page is used for a photograph of a Van Slyke manometer and another for its micro version, and almost a whole page is given to a photograph of the EEL flame photometer, which has been in routine use in virtually all pathology laboratories for many years) Most of the methods for examining blood in a pædiatric hospital are clearly described (the estimation of serum-iron is not among them) Micromethods only are considered, and this excludes many important pædiatric investigations of urine and fæces

Principles of Animal Virology (2nd ed New York and London Academic Press 1960 Pp 490 86*s*)—This book, edited by Sir Macfarlane Burnet, O M, F R S, is very different from Burnet and Stanley's *The Viruses*,[1] and is much more concerned with viruses of men and animals as agents of disease A particularly interesting aspect is its emphasis on the ecology of viruses and on evolutionary aspects of virus development Much of the book is written from a very personal viewpoint, and the references are selective rather than comprehensive Nearly half the text of the first edition, which appeared five years ago, has been rewritten

Preventive Medicine and Public Health (4th ed London H K Lewis 1960 Pp 316 27*s* 6*d*)—It is no easy matter in these days to write a universally acceptable student textbook on public health, there is still so much diversity of opinion about the legitimate scope of the subject and so much variation from school to school in attention given to it Prof Fred Grundy's book aims to be an introduction for students and practitioners and it obviously meets a want, for it is now in its fourth edition in ten years The book is necessarily simple in its approach, and some of its pictures could perhaps be shed without much loss, but it does provide an outline of basic principles and for the zealous it offers suggestions for further reading

Hypnoanalysis (New York Grove Press London John Calder 1960 Pp 342 16*s* 6*d*)—Dr Lewis R Wolberg's wide experience of hypnosis is well known, and some of his writings have become classics This paperback, which is a reprint of a 1945 Grune & Stratton edition, is devoted to the use of hypnotic techniques during psychoanalysis, in this case Freudian The first 136 pages describe the treatment of one patient, then follows a 21-page "dynamic formulation" by Dr A Kardiner, and in the final 179 pages Dr Wolberg suggests the various ways in which hypnosis can be of use in psychoanalytic treatment The case-report is certainly of great interest, notwithstanding the doubt in diagnosis, and Dr Wolberg writes better than most analysts, but the work will do little to convince the sceptical Practitioners who use either of these techniques will find the book interesting, but there must be serious reservations about presenting this new edition to the large lay readership for which it is presumably intended

THE LANCET

LONDON 5 NOVEMBER 1960

Coming Home and Going Abroad

ON achieving independence, a Colony naturally wants to have all its services manned by its own people, and that is something to which every new nation should look forward. But commonly the wellbeing and progress of Colonies have depended largely on the devoted work of administrative and professional officers from overseas, and usually these ought to go on with that work until there are enough properly qualified indigenous officers to replace them. Unfortunately the insecurity of a new regime may lead to an exodus of many of the men and women whom the new country will most need in the next few years. The anxieties of a Civil Servant in a country likely to become self-governing are well depicted in the white-paper[1] issued last week:

> “ the sense of vocation which led him into the Public Service in an overseas territory still remains, but he is beset by uncertainty as to the extent to which he will be able to fulfil it under the new conditions. his status in public affairs is changing and very often he and perhaps his family also are subject to discomforts stemming naturally from a period of rapid political change, and until reassurance is given him on the shape of his future he must live through a period of extreme doubt about the years ahead.”

To prevent the “tragic waste of human skills and wisdom” inevitable where a service runs down through departure of its key members, the British Government, as announced last July,[2] are offering ten-year agreements to most Colonial territories by which the territory need pay little more to employ someone from overseas than to employ one of its own nationals.[3] In respect of some 21,000 officers of the Overseas Civil Service (appointed by the Colonial Office or the Crown Agents) the Government will be responsible (1) for the expatriation or inducement element often added to basic salaries to attract overseas candidates, (2) for the corresponding part of the pension, (3) for education and children's allowances, (4) for half the cost of leave passages, and (5) for half the cost of compensation payable for premature retirement. While this excellent scheme can be looked on as an act of justice towards people who have been encouraged to take overseas appointments under the Crown, it is also much more. It is an important offer of assistance, during the transition period, to territories which may see the advantages of retaining expatriate officers but might otherwise be unable to keep them. The cost to Britain is estimated at between £12 million and £16 million a year.

Two years ago at the British Medical Association's conference on overseas appointments,[4] one speaker said bluntly that if men are expected to go and work in the Colonial Service, arrangements must be made for them when they come back. An attractive suggestion which is firmly turned down in an appendix to the white-paper is that the Civil Services at home and abroad should be unified, so that members could expect a full career, if not in the Colonies then at home. But in point of fact the home Civil Service, with an administrative staff of less than 2500, can offer comparatively few openings to men returning from abroad, and the vacancies now likely to be offered to such men by other Colonies will usually be in a basic grade, and for only one or two tours of service. The creation of a unified service based on the United Kingdom would, it is felt, give a false impression, because it could create no jobs for which members of the Overseas Civil Service are not already eligible. Though some of these will enter the home Civil Service, or the Foreign Service, or may be assigned to other countries under technical-assistance agreements or similar arrangements, they cannot be sure of such employment, and for this reason the Colonial Office in July, 1957, set up an Overseas Services Resettlement Bureau to find them, if need be, alternative posts. Of 1710 applicants the bureau has so far found employment for over 1000—about 500 of them in the past year. The Government hope that “the knowledge that the Bureau will be there to assist them when required will both encourage officers to continue their overseas service, and new recruits to join it.”

To the returning doctor even less than to the administrator can the Government guarantee a post at home, and latterly the difficulty of getting one has been a misfortune both to those who applied and to the public which has often been denied their services. The Government's own medical establishment is small and specialised, and the Ministry of Health, even when it accepts a moral obligation to get a particular specialist appointed or reappointed to the National Health Service, finds regional hospital boards properly reluctant to choose anyone other than the best applicant for the job. If the specialist has difficulty in establishing himself in this country, the difficulty can be even greater for general-duty officers who, though they may have been doing general practice at a high level, have usually been unable to secure National Health Service practices against the competition of younger men who have stayed here. The gloom over our failure to reabsorb so many of our able people who have had the courage and enterprise to work abroad was epitomised in the statement of a speaker, two years ago, that he could not see how general-duty medical officers returning from Colonial service can fit in anywhere at any level in our medical services. And this gloom seems as inspissated as ever, causing even the most sanguine to speak of this problem of medical resettlement as largely insoluble. But are we not in fact dealing with a hangover rather than an incurable illness? If, as LAFITTE and SQUIRE[5] say, this country is shortly going to wake up and find

Reviews of Books

The Problem of Acute Hypothermia

Editor P M Starkov Translated from the Russian by R E Hammond Editor of English edition E Neil, M D, professor of physiology, Middlesex Hospital Medical School London Pergamon Press 1960 Pp 329 70*s*

This book contains the results of many years research in Professor Starkov's department in Omsk There are twenty-eight articles by the fourteen workers concerned, and they are all physiological, though the hope is expressed that some of the conclusions may be put to practical use The subject titles alone make interesting reading, for, as might be expected, they imply a quite different approach to the physiology of hypothermia from that in the Western world, where much of the work has been planned pragmatically, according to the needs and problems of the operating-theatre, and not so much concern, perhaps, is felt about the basic differences between the body functions at normal temperature and those revealed during hypothermia Physiologists will therefore welcome the results of study on such fundamentals as cold effects on blood-flow in limbs and viscera, on the effects of direct cerebral cooling, and the use in hypothermia investigation of the values accorded by such familiar parameters as those of the heart-lung preparation, decerebrate cat, isolated rat uterus, and skeletal muscle Behaviour and conditioned reflexes in puppies and adult dogs are subjects of natural interest to Russian physiologists, and the response of these nervous patterns to hypothermia is the subject of one of Professor Starkov's own articles

The publishers regret that for speed and economy of production the text is in typescript photolithography, but the quality of the pages is even and good, and the content more than makes up for any deficiency The translation is commendably clear

Lectures on Hæmatology

Editor F J G Hayhoe, M D, M R C P, department of medicine, University of Cambridge London Cambridge University Press 1960 Pp 247 60*s*

These lectures were delivered at Cambridge in December, 1959, at a course for physicians and clinical pathologists "having hæmatology as one of their main interests" Four of these lectures will interest any hæmatologist J V Dacie gives some facts from his unique experience in hæmolytic anæmia, W M Davidson provides an excellent account of iron metabolism and treatment, G Wetherley-Mein describes interestingly and practically what is meant by "myeloproliferative syndromes", and R M Hardisty makes a gallant attempt to bring together in a moderately coherent account what we now know about hæmostatic processes The other lectures are good, sometimes very good, reporting work that will be familiar to many hæmatologists R H Girdwood on megaloblastic anæmias, George Discombe on transfusion hazards, and J C White on hæmoglobin variants summarise their already published work Dr Hayhoe himself draws on some pages from his recent book on leukæmia Richard Doll writes on the incidence of leukæmia and the significance of environmental factors, D A G Galton on the chemotherapy of leukæmia, G I C Ingram on congenital and acquired disorders of blood coagulation, and J F Ackroyd on the pathogenesis of purpura H E M Kay brings together a useful summary of published results on attempts to use marrow transplants in the treatment of leukæmia

This sort of book falls between two stools the specialist in hæmatology will be interested only in the first four lectures we mentioned, the more general physician or pathologist with a main interest in hæmatology will hardly wish to buy a set of lectures that will need revision in a short time, especially when he can buy a whole textbook of hæmatology, containing nearly everything in this volume and a lot more, for rather less This volume is to be one of a series why not publish the others in a less expensive form—say, paper back with plastic binding and without some of the illustrations, none of which, in this hæmatology volume, are really necessary ?

Chemical Micromethods in Clinical Medicine

R H Wilkinson, M D, assistant chemical pathologist, The Hospital for Sick Children, London Oxford Blackwell Scientific Publications 1960 Pp 121 40*s*

Emphasis on micromethods in chemical pathology has increased steadily during the past twenty years It was gradually realised that blood-sugar and blood-urea were not the only substances that could be measured using capillary blood and that it was obviously more considerate and convenient to take small samples of capillary blood by needle-prick than larger ones from a vein by syringe It has also become clear that small amounts of heparinised blood may yield as much plasma as larger amounts of clotted blood can yield serum These considerations apply particularly to pædiatrics, and in this country notable contributions to microchemical methods have come from The Hospital for Sick Children, Great Ormond Street, and some very important ones from the author of this little book There are only about 100 pages of text, of which 10 are taken up by illustrations, not all of them essential (a page is used for a photograph of a Van Slyke manometer and another for its micro version, and almost a whole page is given to a photograph of the EEL flame photometer, which has been in routine use in virtually all pathology laboratories for many years) Most of the methods for examining blood in a pædiatric hospital are clearly described (the estimation of serum-iron is not among them) Micromethods only are considered, and this excludes many important pædiatric investigations of urine and fæces

Principles of Animal Virology (2nd ed New York and London Academic Press 1960 Pp 490 86*s*)—This book, edited by Sir Macfarlane Burnet, O M, F R S, is very different from Burnet and Stanley's *The Viruses*,[1] and is much more concerned with viruses of men and animals as agents of disease A particularly interesting aspect is its emphasis on the ecology of viruses and on evolutionary aspects of virus development Much of the book is written from a very personal viewpoint, and the references are selective rather than comprehensive Nearly half the text of the first edition, which appeared five years ago, has been rewritten

Preventive Medicine and Public Health (4th ed London H K Lewis 1960 Pp 316 27*s* 6*d*)—It is no easy matter in these days to write a universally acceptable student textbook on public health, there is still so much diversity of opinion about the legitimate scope of the subject and so much variation from school to school in attention given to it Prof Fred Grundy's book aims to be an introduction for students and practitioners and it obviously meets a want, for it is now in its fourth edition in ten years The book is necessarily simple in its approach, and some of its pictures could perhaps be shed without much loss, but it does provide an outline of basic principles and for the zealous it offers suggestions for further reading

Hypnoanalysis (New York Grove Press London John Calder 1960 Pp 342 16*s* 6*d*)—Dr Lewis R Wolberg's wide experience of hypnosis is well known, and some of his writings have become classics This paperback, which is a reprint of a 1945 Grune & Stratton edition, is devoted to the use of hypnotic techniques during psychoanalysis, in this case Freudian The first 136 pages describe the treatment of one patient, then follows a 21-page "dynamic formulation" by Dr A Kardiner, and in the final 179 pages Dr Wolberg suggests the various ways in which hypnosis can be of use in psychoanalytic treatment The case-report is certainly of great interest, notwithstanding the doubt in diagnosis, and Dr Wolberg writes better than most analysts, but the work will do little to convince the sceptical Practitioners who use either of these techniques will find the book interesting, but there must be serious reservations about presenting this new edition to the large lay readership for which it is presumably intended

Coming Home and Going Abroad

ON achieving independence, a Colony naturally wants to have all its services manned by its own people, and that is something to which every new nation should look forward But commonly the wellbeing and progress of Colonies have depended largely on the devoted work of administrative and professional officers from overseas, and usually these ought to go on with that work until there are enough properly qualified indigenous officers to replace them Unfortunately the insecurity of a new regime may lead to an exodus of many of the men and women whom the new country will most need in the next few years The anxieties of a Civil Servant in a country likely to become self-governing are well depicted in the white-paper [1] issued last week

> “ the sense of vocation which led him into the Public Service in an overseas territory still remains, but he is beset by uncertainty as to the extent to which he will be able to fulfil it under the new conditions his status in public affairs is changing and very often he and perhaps his family also are subject to discomforts stemming naturally from a period of rapid political change, and until reassurance is given him on the shape of his future he must live through a period of extreme doubt about the years ahead ”

To prevent the “ tragic waste of human skills and wisdom ” inevitable where a service runs down through departure of its key members, the British Government, as announced last July,[2] are offering ten-year agreements to most Colonial territories by which the territory need pay little more to employ someone from overseas than to employ one of its own nationals [3] In respect of some 21,000 officers of the Overseas Civil Service (appointed by the Colonial Office or the Crown Agents) the Government will be responsible (1) for the expatriation or inducement element often added to basic salaries to attract overseas candidates, (2) for the corresponding part of the pension, (3) for education and children's allowances, (4) for half the cost of leave passages, and (5) for half the cost of compensation payable for premature retirement While this excellent scheme can be looked on as an act of justice towards people who have been encouraged to take overseas appointments under the Crown, it is also much more It is an important offer of assistance, during the transition period, to territories which may see the advantages of retaining expatriate officers but might otherwise be unable to keep them The cost to Britain is estimated at between £12 million and £16 million a year

Two years ago at the British Medical Association's conference on overseas appointments,[4] one speaker said bluntly that if men are expected to go and work in the Colonial Service, arrangements must be made for them when they come back An attractive suggestion which is firmly turned down in an appendix to the white-paper is that the Civil Services at home and abroad should be unified, so that members could expect a full career, if not in the Colonies then at home But in point of fact the home Civil Service, with an administrative staff of less than 2500, can offer comparatively few openings to men returning from abroad, and the vacancies now likely to be offered to such men by other Colonies will usually be in a basic grade, and for only one or two tours of service The creation of a unified service based on the United Kingdom would, it is felt, give a false impression, because it could create no jobs for which members of the Overseas Civil Service are not already eligible Though some of these will enter the home Civil Service, or the Foreign Service, or may be assigned to other countries under technical-assistance agreements or similar arrangements, they cannot be sure of such employment, and for this reason the Colonial Office in July, 1957, set up an Overseas Services Resettlement Bureau to find them, if need be, alternative posts Of 1710 applicants the bureau has so far found employment for over 1000—about 500 of them in the past year The Government hope that “ the knowledge that the Bureau will be there to assist them when required will both encourage officers to continue their overseas service, and new recruits to join it ”

To the returning doctor even less than to the administrator can the Government guarantee a post at home, and latterly the difficulty of getting one has been a misfortune both to those who applied and to the public which has often been denied their services The Government's own medical establishment is small and specialised, and the Ministry of Health, even when it accepts a moral obligation to get a particular specialist appointed or reappointed to the National Health Service, finds regional hospital boards properly reluctant to choose anyone other than the best applicant for the job If the specialist has difficulty in establishing himself in this country, the difficulty can be even greater for general-duty officers who, though they may have been doing general practice at a high level, have usually been unable to secure National Health Service practices against the competition of younger men who have stayed here The gloom over our failure to reabsorb so many of our able people who have had the courage and enterprise to work abroad was epitomised in the statement of a speaker, two years ago, that he could not see how general-duty medical officers returning from Colonial service can fit in anywhere at any level in our medical services And this gloom seems as inspissated as ever, causing even the most sanguine to speak of this problem of medical resettlement as largely insoluble But are we not in fact dealing with a hangover rather than an incurable illness? If, as LAFITTE and SQUIRE [5] say, this country is shortly going to wake up and find itself extremely short of doctors, those who might be willing to reduce the shortage can take new heart

[5] Lafitte F Squire J R. *ibid* Sept. 3, 1960 p 538

Similarly the apparent risks of going abroad for a few years, on secondment or otherwise, may begin to bulk less large in the minds of candidates The Government are in favour of secondment from their own services here, and propose to have talks with representative bodies of employers " to seek their agreement to releasing staff on loan "—paying " in appropriate cases the differential between the terms of the overseas appointment and the local salary " If there are still senior members of the profession who are inclined to discourage their juniors from going abroad, we hope they will give thought to the white-paper's correct statement that service overseas affords " opportunities to do interesting work in a new environment, opportunities to exercise individual initiative and responsibility at an earlier age than is usual here, opportunities to develop personal qualities of self-reliance, leadership and adaptability arising from the wide variety of tasks to be undertaken opportunities to make an individual contribution to the development of a new country " Even more, perhaps, we hope they will read the remarkable review of the African situation, by Dr H S GEAR, which we publish this week Though GEAR credits colonialism with having given Africa a phase of social stability with a rising economy, and recognises that the main medical contribution has been, and still is, made by the official services, he is concerned mainly with the unofficial aspects of a system which hitherto has been continually nourished and refreshed from Europe " Medicine's true teachers and disciples give more to Africa," he says, " than medical care in a hospital or clinic ", and Western medicine should not overlook the need for this broader interpretation of its possible service " It should guide Africa to create people who are good doctors and nurses, but are also prepared to follow fearlessly the principles founded over many difficult generations in Europe and America "

Protein in Hyaline Membrane

THE chief component of the hyaline membrane found on histological examination of the lungs of premature infants who have died shortly after birth was once believed to be inspissated material derived from the amniotic fluid or vernix caseosa, and the term " vernix membrane " was used for some years [1] It now seems that a fundamental disorder of the pulmonary circulation plays a part in the formation of the membrane,[2] protein being extravasated from the pulmonary vessels into the neighbouring air-spaces and then forced by inspiration *into a membrane lining the walls of these spaces*

While most agree that the bulk of the membrane is composed of protein, there is still some difference of opinion as to its origin and nature LYNCH [3,4] initially suggested that the membrane represented a dried and concentrated secretion of the respiratory bronchioles and alveolar ducts Further work indicated that the membrane included hæmoglobin,[5] but the bulk of it was composed of fibrin [6,7] All these investigations reinforced the idea that the components of the membrane were derived from the blood-stream The various cardiovascular factors associated with hyaline-membrane formation were analysed by SHANKLIN [8] in a series of 335 premature infants He found that membrane formation was significantly more frequent in association with cardiac malformation that increased the pulmonary blood-flow The stages of the development of the pulmonary lesion were thought to be increased pulmonary blood-flow, left ventricular failure, pulmonary œdema, and membrane formation The possibility that maternal factors may play a part in the presumed circulatory disturbance has been investigated by COHEN et al ,[9] whose work seems to indicate that membrane formation is commoner when the pregnancy has been complicated by toxæmia and especially by antepartum hæmorrhage From time to time it has been claimed that the frequency of hyaline membrane is increased in infants delivered by cæsarean section [10], but COHEN et al conclude that any such increase is limited to pregnancies where bleeding has occurred before delivery

The composition of hyaline membrane has been investigated by BUCKINGHAM and SOMMERS [11] They regard the structure as laminated acellular layers of eosinophilic material apposed to the walls of alveolar ducts, alveoli, and terminal bronchioles Ultraviolet microscopy showed that the material closely resembled plasma-protein or cell cytoplasm, in addition, some nucleoprotein was thought to be present Membranes produced experimentally by exposure of mice to oxygen had a similar composition The membranes thus seemed to comprise cytoplasmic material, hæmoglobin, polymerised fibrin, nucleoprotein, and mucoprotein These workers were impressed by degenerative changes in the bronchiolar epithelium, which they believe contribute to membrane formation Hyaline membrane may possibly be associated with hypersecretion of alveolar lining substance [12] which raises the question whether abnormal autonomic nervous stimulation enhances its formation, not only by promoting pulmonary œdema but also by increasing secretory activity in the terminal air-passages

Although highly specialised techniques have revealed fibrin in hyaline membrane, this does not stain for fibrin by ordinary histochemical methods It has been shown, however, that a hyaline material is formed when certain acid mucopolysaccharides react with plasma-proteins [13,14], and the possibility that a similar mechanism may operate in hyaline-membrane formation has been investigated by CARONE and SPECTOR,[15] who induced pulmonary œdema in rats by means of α-naphthyl thiourea and then introduced, by the endotracheal route, various substances including dextran sulphate, nasal mucus, meconium, and concentrated amniotic-fluid suspension All these substances contain acid mucopolysaccharides, and all produced a membrane which had similar tinctorial properties to those of the membrane found in the human lung and which also failed to stain for fibrin This suggests that, if hyaline membrane is indeed largely composed of fibrin, then this is probably in a polymerised form Similar membranes were also produced when these acid mucopolysaccharides were introduced via the trachea together with plasma-protein in animals not previously given α-naphthyl thiourea

Even if the membrane is largely composed of fibrin, the reason for the chain of events leading up to fibrin precipitation in the lungs of some infants but not of others still has to be found A possible clue is afforded by the work of LIEBERMAN[16] As a result of preliminary studies he postulated that a deficiency of lung plasminogen-activator activity predisposed certain infants to hyaline-membrane formation. It could be objected that such a low enzyme activity might result from exhaustion of supply by the disease process itself[17], but any such doubt has been largely settled by LIEBERMAN and KELLOGG,[18] who have now evolved an improved technique for measuring tissue plasminogen-activator activity They describe their findings in specimens obtained from 61 fœtuses and newborn infants, comprising 15 cases of hyaline membrane and 46 controls All but 2 (4%) of the control series showed plasminogen-activator activity, and none showed any inhibitor activity By contrast none of the 15 membrane cases showed activity when lung cubes were examined, but in 2 out of 11 cases homogenised tissue showed some activity The remaining 9 cases studied by tissue homogenisation showed no activator activity, and in 8 of them evidence of inhibitor activity was found These results confirm the previous observation of defective plasminogen-activator activity in association with hyaline membrane The inhibitor of the enzyme, found in most of the affected lungs, may explain the lack of success which has attended the therapeutic use of fibrinolytic agents in affected babies In a preliminary communication in our present issue Dr FLEMING and his associates at the National Naval Medical Center at Bethesda report apparent absence of plasminogen activator in the lungs of two men whose hyaline membrane followed "total body irradiation", and their findings in dogs were consistent with the view that irradiation produces a potent inhibitor of activation LIEBERMAN and KELLOGG suggest that, in infants, the enzyme defect may be genetically determined

SETNIKAR et al[19] suggested that an alveolar transudate is an essential part of amniotic fluid. If this is so, a rich source of fibrin is contained in the fœtal lung, and, if fibrinolytic activity is defective or absent, fibrin deposits may gradually accumulate and form into membranes after the onset of respiration Again, deficient proteolytic activity in the lung may interfere with the alveolar lining layer and so affect the surface tension in the pulmonary air-spaces Such an increase in the surface-tension is thought to promote atelectasis[20]

Although much work is being done on hyaline membrane, it is abundantly clear that our understanding of its formation is still deficient, and no effective remedy is in sight

Troubled Families

> " the State's principal duty is to assist the family in carrying out its proper functions "

So say the Ingleby Committee whose report,[21] published last week, gives important and far-reaching advice on means of helping delinquent, disturbed, and neglected children under 17 Unfortunately cause and prevention did not enter into their terms of reference, but it is clear that the committee believed that the family and the relationships therein were the primary causes of later difficulties, whatever secondary influences may subsequently play a part—an emphasis which colours the recommendations throughout The parents, as much as the disturbed child, need to alter their ways, and the committee have wisely regarded the child as a person to do things *round* rather than the patient or sinner to do things *to*

Set up by the Home Secretary in 1956, the committee[22] record that at that time falling delinquency-rates and fewer maintenance and affiliation orders set a scene which, if not rosy, was at least hopeful But since then this trend has been dramatically reversed, so that the Ingleby recommendations gain much in significance and will be given prompt Governmental scrutiny

Considering first the ways in which help reaches the family, the report notes that inter-service rivalry has, in the past, impaired coordination and delayed the arrival of appropriately trained workers Thus, while the committee welcome the help of almost any agency in bringing troubled families and children to notice, diagnosis and treatment require tactful handling and, very often, special skills not always found among those who concern themselves with the personal affairs of others A reorganisation of the various family services is called for, with the establishment of an independent "family bureau" responsible only to the clerk to the local authority Detailed consideration of local-government changes was beyond the committee's terms of reference and they urge further study of this matter, bearing in mind that differing local circumstances will call for flexibility in legislation designed to ensure efficient coordination The report declares that " there should be a general duty laid upon local authorities to prevent or forestall the suffering of children through neglect in their homes," and such authorities should be required to submit schemes for Ministerial approval The only bodies, the report goes on, with the power to bring a case before the courts should be the police and the local authority—a move, it seems, away from the sometimes harmful multiplicity of authorities bearing on the family This proposal, which removes such power from the National Society for the Prevention of Cruelty to Children, is likely to be a contentious one when debated in Parliament and elsewhere, but it is in tune with the legitimate trend towards professionalism in social work The days of the keen but untutored amateur are passing, and rightly so The reluctance of the committee to widen " juvenile liaison schemes ", run by the police for cautioned offenders, springs from similar judgment

[21] Report of the Committee on Children and Young Persons Cmnd. 1191 H.M Stationery Office. Pp 179 8s
[22] The members were Lord INGLEBY (chairman), Lady ADRIAN, Hon. Mrs P L AITKEN, Mr R. H BLUNDELL, Mr DONALD FORD, Dr R. M. JACKSON, Mrs M. M C KEMBALL, Mr G H. MCCONNELL, Prof ALAN MONCRIEFF, Viscountess RIDLEY, Dr P D SCOTT, Mr G A. WHEATLEY, Alderman D T WILLIAMS, and Mr J P WILSON

Turning to jurisdiction, the committee note the trend, over the past century or so, towards separate provision under the criminal law for the young and, more and more, towards emphasis on the welfare of the child as the overriding concern This has led, the committee believe, to inconsistencies The principle of criminal responsibility and punishment for a certain act in a judicial setting has become uncertainly combined, by statute, with the obligation to serve the child's best and broadest interests Thus a trivial offence may, when the full appalling family circumstances become known to the court, lead to a seemingly severe and drastic disposal Furthermore, the widening of the court's function in 1908 and 1933 permitted a child to be sent to an approved school (a severe punishment very often) for the non-criminal offences of being " beyond control " or in need of " care or protection " In rethinking the place of juvenile courts the committee concluded cautiously that, however much a child may seem likely to benefit from interference by the State, compulsory intervention should not be applied except for the clearly defined and well-known reasons that already obtain The basic pattern of courts, too, with lay justices still finds favour with they committee, though they concede some virtues to the non-judicial tribunal

The trend away from criminal jurisdiction, however, should be urged forward, notably by raising the minimum age of criminal responsibility from 8 to 12 years, and later perhaps to 13 and 14 Though an important change of principle, the practice of the law would not be as much affected by this as might be imagined Already offending children under 8 may be brought before a court and dealt with as " beyond control " the court, under these proposals, will certainly not allow children to " get off ", indeed by the greater thoroughness of the procedure, Society may expect better protection than before Children under 12 would no longer be charged with an offence, though if such were established (under the usual rules of evidence) it would count towards showing that the child was " in need of protection or discipline "—the new form of words empowering the court to take action The procedure would be swifter (cases would have to be tried within 28 days of detection, save in special circumstances) and more holistic, taking in the whole circumstances of the case The police and local authority would consult before proceedings began Though retaining the power to remove a child from home, the court would do so only when it was satisfied that his needs could not be somehow met without such action, and it would have the additional options of ordering attendance at an attendance centre or study in a remand home Fines and detention in detention centres would be withdrawn, but compensation to a maximum of £100 and/or costs could be demanded Committal to the care of a " fit person " would remain, and parent or guardian could be ordered to enter recognisance to exercise proper care and guardianship The court could also order supervision by a probation officer or other person for up to 3 years From 12 to 17 years procedure would be much as it is now, and the committee did not feel that the age-limit of 17 for juvenile courts should be raised, though they wondered whether a sort of half-way " youth court " for ages 17 to 20 or 21 might be examined further

The committee believe that the court needs to be much more active with the parents, summoning the attendance of both, bringing home to them their share of responsibility, and offering support where it is practicable The verdict of the court—so often a source of grievance—would be explained to them as far as possible Treatment, where compulsory, appears as punishment, and the committee admit that in practice it is impossible to distinguish between them On the other hand, parents would no longer have the right to bring children before the court as " beyond control ", though appeal to the local authority might sometimes have the same effect if no other solution could be found Here, however, parents would not appear in the role of prosecutor, and the need for them to make damaging and rejecting statements towards the child in public would be reduced

The greater part (some 400 out of 550 paragraphs) of the report is a review of administrative detail arising partly from this survey and related to courts, sentences, and corrective institutions Few of the numerous recommendations will be disputed, nor are many of wide interest, important though they are Thus, an adequate course of training is recommended for all juvenile-court magistrates, who should usually be lay people, appointed between about 30 and 40 and retiring at 65 Better court-room accommodation for the children is needed, and the report calls for removal of all legal obstacles to accelerate the disposal of cases involving child witnesses, plus closer liaison with adult courts where necessary The committee approved the attendance-centre principle sufficiently to want to lower the minimum age to 10 and to widen the categories of offenders treated there For detention centres, however, a uniform 3-month sentence should take the place of the present sliding scale between 1 month and 6 (for under 17s only), and the committee are surely right in pressing for compulsory aftercare for a further 6 or 12 months

Approved schools are left much as they are, with a few hopeful calls for inter-school staff discussions and better psychiatric facilities, staff, and aftercare Recent months have made it clear that all is far from well among the approved schools, but from present knowledge it is hard to see how the committee could go further than they have, timid though their recommendations seem Finally, the committee want to extend somewhat the prosecution of cruel parents (to take in mental suffering short of actual derangement) and to increase the penalties to £100 or 6 months' imprisonment or both, though at the same time full use should be made of residential training and social aid

In sum, these proposals do not seem to conflict with any of the many other Governmental reflections of recent years, and they all have it in common that the big problem in realising them is shortage of staff and money (We have now heard from so many committees that a "survey of reports" might help to place the future of our social services in comprehensive perspective) There is little of dynamite in the Ingleby recommendations Juvenile-court organisation, in particular, has been left largely alone, to the disappointment, undoubtedly, of many But the committee have reached a quite surprising degree of unanimity after their 4-year pilgrimage, and few who advocate sweeping changes have given such careful thought to the implications These proposals, in the present state of therapeutic knowledge, are probably as far as we should go and must carry an excellent chance of early Parliamentary acceptance Coming when voluntary acceptance of child and family guidance services is spreading and when compulsory treatment for "psychopaths" is becoming possible under the National Health Service we have now the foundations of an excellent service for children The wisdom of this report cannot be in doubt, and the sooner it all happens, the better it will be for everyone

Annotations

SOCRATES IN HARLEY STREET

SOME two years ago, in a week when medical education was being considered at a formal conference in London, we printed a less orthodox discussion of the same problems in our peripatetic columns It began

> ALCIBIADES Tell me, Socrates, how can we be sure that our doctors are well trained?
>
> SOCRATES Do you think it right, Alcibiades, that we should say of a pudding that it is good or bad?
>
> ALCIBIADES Certainly, Socrates
>
> SOCRATES It must be possible then to distinguish a good pudding from a bad one?

This learned ballon d'essai pleased readers, author and editor Socrates was offered a column of his own, and throughout 1959 under the heading of "Dialogues of Today" he and his disciples debated in our columns some of the social and moral uncertainties of medicine and humanity, of our time and all times Because the dialogues deal with problems which belong not only to medicine and not only to this country, we have reprinted them as a small book (with paper covers)[1] for the consideration of all who enjoy a good argument

The dialogues range from birth control to death control, from ways of constituting a committee to the reasons for constituting a college, from the atomic bomb to less final methods of retirement But if the matter is serious the manner is never heavy No dogmatic conclusions are offered and the reader is left to continue the debate with his own friends—and perhaps with himself The anonymous author admits that he has chosen the conversational form with provocative intent His introductory quotation, borrowed from David Hume, another writer of dialogues, describes dialogue writing as peculiarly suitable for a topic which is obvious but important or for one which is so obscure and uncertain that the human reason can reach no fixed determination with regard to it "Reasonable men," Hume adds, "may be allowed to differ, where no one can reasonably be positive Opposite sentiments, even without any decision, afford an agreeable amusement" We hope that all our reasonable readers will find agreeable amusement with Socrates

CHOLESTATIC VIRAL HEPATITIS

EVEN before the 1939–45 war it was recognised that a varying but small proportion of cases of epidemic viral hepatitis differed from typical cases in the difficulty with which they could be distinguished from cases of extrahepatic biliary obstruction[1] Histologically the liver in such cases was characterised by the extreme mildness of the parenchymal lesions and their restricted focal distribution, the conspicuous features were multiple intralobular plugs of bile and moderate to severe infiltration of the portal tracts with both mononuclear cells and polymorphs Hitherto deviation from the more usual pattern of the disease has not been satisfactorily explained

Dubin et al,[2] on the basis of their experience at a U S Army Hospital in the years 1951–53, suggest that the cholestatic form of hepatitis may be due to a variant of the usual virus Their clinical material comprised 93 cases of viral hepatitis in which biopsy of the liver was undertaken within twenty-one days of the onset of jaundice By means of clearly defined criteria these cases were classified into four types Type A showed the diffuse necrosis with very slight bile stasis that is typical of classical viral hepatitis Type B was similar, but intralobular plugs of bile indicated some added cholestasis Type C was characterised by focal distribution of the parenchymal lesions and predominance of cholestasis In type D parenchymal necrosis was negligible, the changes consisting almost entirely in bile stasis and cellular infiltration of the portal tracts Patients with lesions of types A or B were regarded as having classical viral hepatitis, and those with lesions of types C or D as having the cholestatic form When the cases were classified into serum hepatitis and infective hepatitis according to whether or not the patient had received a transfusion of blood or blood product in the six months preceding the appearance of jaundice, correlations appeared between serum hepatitis and the classical picture and between infective hepatitis and the cholestatic form This, however, was contrary to the results of all previous studies, and further analysis showed that the more probable correlation was between the variety of the disease and the area where it was contracted Thus of the 36 patients with serum hepatitis, of whom only 5 belonged to the cholestatic group, 30 had been transferred with their disease from the Far East, whereas of the 54 patients with infective hepatitis, of whom 21 belonged to the cholestatic group, only 8 were from the Far East and 46 were of local origin All 21 cases of cholestatic hepatitis occurred among the 46 local cases of infective hepatitis which suggests that the local epidemic virus had a remarkable predilection for inducing the cholestatic form of the disease Since no other factors, such as exposure to drugs or toxins, were apparently responsible for this distribution of the cholestatic form, Dubin et al feel justified in attributing it to some special property of the virus The even higher incidence of this form in the epidemic in Delhi described by Smetana [3] can be taken as evidence of widespread distribution of this variant of the infective-hepatitis virus

THE GENE

IN a British Association Granada lecture delivered in London on Sept 27, Dr G W Beadle, professor of biology at the California Institute of Technology, surveyed mechanisms of heredity There seems to be no doubt that it is the cell nucleus that contains the primary hereditary message, the gene being the simplest unit of biological instruction, and some 10^4–10^6 of them being necessarily present in every human egg The only nuclear constituents of sufficient complexity to carry such a message are the proteins (linear polymers of some 20 different amino-acids) and the desoxyribonucleic acids (D N A) (linear polymers of only 4 different nucleotides) Evidence favouring D N A as the carrier arose initially from the demonstration that bacterial transforming factors (which cause a typical inherited change in some pneumococci) were composed almost entirely of D N A ,[4] but perhaps the most direct proof came from a study of a bacterial virus with inheritance characteristics known to be particulate These bacteriophages consist of a protein coat surrounding a core of D N A , and electron microscopy had suggested that the protein coat did not enter the cell during the process of infection The protein coat was therefore labelled with ^{15}N and the D N A with ^{32}P, and it was conclusively shown that only the D N A entered the cell Thus since these viruses have genes, and since only viral D N A entered, the viral genes must be D N A

The double-stranded D N A molecule,[5] where the sequence of nucleotide units in one strand automatically determines the complementary sequence of its partner, gave a clear indication of how accurate replication could occur provided that sufficient energy was available to separate the two strands by some sort of untwisting process [6] There is certainly enough D N A in a single human egg to carry all the required information, for about 10^{10} nucleotide units exist in the 46 chromosomes of the fertilised egg (ignoring the sex chromosomes), and such a number is probably sufficient to encode the contents of some 500 large books

The gene, then, can be thought of as a segment of the D N A chain, perhaps some 1000 nucleotide pairs in size, and the process whereby such a gene may direct the synthesis of an enzyme involves transferring the code to ribonucleic acid (R N A) (known to be associated with the chromosomes at certain times) by some kind of template system The nuclear R N A then passes to the cytoplasm, where it becomes incorporated into the microsomes Special segments of this R N A bind and activate specific aminoacids, which are thereby held in the correct order for the synthesis of the particular enzyme This type of synthesis probably occurs only when the enzyme substrate is present—so providing a necessary control to prevent every cell from undertaking all possible syntheses In this way differentiation may be controlled by environment A clear example of such genetic control of enzyme synthesis is the inherited condition of galactosæmia, where the patient wholly lacks the enzyme which changes galactose into a usable form

Mutations can be thought of as alterations of the sequence of nucleotides in the genic D N A either chemically (for example, nitrous acid changes D N A amino groups into hydroxyl groups and so upsets the hydrogen bonding on which accurate replication is thought to depend) or spontaneously under the influence of natural radiations Only occasionally, however, does such a mutation lead to an organism of increased reproductive fitness and so to a permanent evolutionary change

Professor Beadle ended by suggesting that paths now seem open, beginning with a universe of hydrogen, to an evolution through other elements, simple inorganic and then organic compounds, then through more complex organic systems to polynucleotides and proteins, the simple virus-like molecules, simple cellular systems, and finally to man himself

FROZEN BLOOD FOR TRANSFUSION

THE Cohn fractionator [1] is designed to separate individual half-litre units of blood into the component parts—red cells, platelets, and plasma—and to wash the red cells free from plasma It consists of a bowl centrifuge whose temperature can be kept constant, and whose bowl and associated containers can be sterilised Haynes et al have been using this machine for the long-term preservation of blood for transfusion The cells are washed with solutions containing up to 50% glycerin, then frozen at −80°C or −120°C, and after storage for 1 to 44 months thawed, deglycerinised, and reconstituted with an appropriate diluent According to requirements, the cells can be resuspended in saline, their own serum which has also been frozen, or 5% human albumin in an isotonic salt solution, to which can be added, as needed, buffers, globulin fractions, or components of clotting systems Of the red cells taken from the donor, 82% reach the recipient, and these seem to survive in his circulation as long as fresh cells Results have been so satisfactory that this frozen and reconstituted blood has been in routine use at the U S Naval Hospital in Chelsea, Mass , for more than a year So far over 1000 units have been administered without trouble, Haynes et al remark that febrile reactions have been remarkably few, and hepatitis has been absent

The cost of these benefits is considerable Rough costing suggests a figure of about £6 per unit, excluding building and heating, and a team of six workers using two fractionators can process only 200 units monthly. Many London hospitals, dealing with 15,000–20,000 inpatients a year, may need over 500 units of blood in a month. This would call for five fractionators and a team of twelve or fifteen, besides the existing staff of two technicians and a part-time doctor. The cost of each bottle of blood for transfusion would rise from the present £1 2s–1 5s to something like £6–7. Further, such hospitals use blood chiefly to treat unexpected hæmorrhage, relatively little blood is used for elective surgery or for the treatment of anæmia, so a large supply of fresh, or already reconstituted, blood would have to be kept on hand. Now that the incidence of post-transfusional hepatitis has been reduced to 1 in about 800 transfusions, there seems to be little point in providing this expensive equipment for individual hospitals.

On the other hand, there may be a case for setting up a few processing units for blood of unusual groups. Very rare red cells such as -D-, could be reserved against need, and a moderate stock of blood of the less common groups which may be needed for extracorporeal circulations could be established. In the past few months, because many regular donors have been on holiday, there has been a shortage of blood of all kinds,[3] which fortunately has led to nothing more serious than the postponement of elective operations for a week or two, it might be possible to store blood collected in the autumn, winter, and spring against the needs of the summer. But such a project is bound to be expensive, and it is doubtful whether it would produce more benefits than would half the money spent on something else.

SHINGLES AND CHICKENPOX

Wesselhoeft,[4] in delivering the sixteenth Charles Value Chapin oration, took the opportunity to review past and present ideas about the nature of chickenpox and shingles, and gathered into a valuable bibliography accounts of experiments and observations from many sources. Those who thought that Weller and Coons [5,6] in the laboratory, and Hope-Simpson [7] in the field, had convinced the medical profession of the unitary nature of varicella, however contracted, may be disappointed by the note of agnosticism on which he ended his address.

The journals tend to give more space to rare than to common events, and this predominance may disturb the balance of a comprehensive review. Rare occurrences are informative and must not be dismissed, but, still less, the common pattern of behaviour of a disease should not be overlooked. There is a real danger of missing the wood for the trees, especially rare trees.

The common relation between shingles and chickenpox is as follows. Both can cause chickenpox in susceptible contacts, though the risk of this happening after contact with shingles is less than a third of its happening after contact with chickenpox. In either case the resultant disease is, by clinical, epidemiological, and virological criteria, ordinary chickenpox. On the other hand, neither chickenpox nor shingles gives rise to an attack of shingles in contacts, whatever their previous history of either disease. This is the usual pattern shorn of rare exceptions, and it determines the epidemiological behaviour found in practice—namely, that chickenpox appears in epidemics when aggregations of susceptible persons are effectively exposed to cases of chickenpox or shingles, but that shingles does not itself appear in epidemics and is independent of epidemics of chickenpox.

For the "dualist" who holds that there is a distinction between ordinary and zoster-induced varicella there is a difficulty that seems never to have been adequately considered. How far backwards must the antecedents of a case of chickenpox be traced before it can with certainty be classified as "ordinary" and not "zoster-induced"? Are ten generations of ancestry to be considered adequate evidence, or a hundred or a thousand? One observer traced back an outbreak for twelve months and classed it as "ordinary varicella". Had he, by pushing the inquiry still further into the past, found that the outbreak in fact stemmed from an original case of shingles, he would have been compelled to reclassify it as one of "zoster-induced varicella". Except in remote areas it is seldom possible to back-track in this way with any certitude, and, in such remote regions, outbreaks are commonly found to stem either from a local case of shingles or from a case of chickenpox imported from more crowded areas where further investigation of the lineage of the virus is difficult. On all the evidence, it should surely be conceded that there is only one chickenpox, which can be caught either from another case of chickenpox or from a case of shingles.

Much remains to be understood, foremost the nature of shingles itself. If, as seems likely, it is due to the reactivation of latent chickenpox virus, where in the body is the latent remnant? Do all who have had chickenpox depend upon the survival of this latent brood for the preservation of their immunity? How is the symbiosis disturbed so that a harmony of maybe fifty years breaks down, the eruption develops in a dermatome, and infectious chickenpox virus escapes into the environment? On questions such as these light may be shed by the more unusual happenings, the anomalies and exceptions to the common pattern described above. The least uncommon anomaly is the occurrence, usually in children, of a zoster during a primary attack of chickenpox—an apparent exception to the rule that contact with chickenpox does not give rise to shingles. Much rarer are those cases in which shingles in an adult appears to have been caused by contact with another case of shingles or a case of chickenpox. How uncommon this is was shown by a prospective study of thousands of contacts of cases of chickenpox and shingles of whom not one developed shingles. Nevertheless cases have occasionally been recorded in circumstances that make them very unlikely to be fortuitous. Again there are a few records of attacks of zoster-induced varicella failing to protect against subsequent exposure to chickenpox. All such rarities must find their explanation in a more complete understanding of the two diseases, but in the meantime they should not be allowed to obscure the picture which is already emerging.

Even if some laboratory refinement should in the future discover a recognisable peculiarity of virus newly released by an attack of shingles from its intracellular confinement, the interesting observation would no more disturb the ætiological picture than a similar finding in spirochætes from late cases of syphilis would unsettle our present conception of that disease.

The Wider World

MEDICINE AND THE NEW AFRICA *

The Passing of Colonialism South of the Sahara

H S GEAR
M D, B Sc W'srand, D P H, D T M & H
FORMERLY CHAIRMAN, EXECUTIVE BOARD, WORLD HEALTH ORGANISATION, DEPUTY CHIEF HEALTH OFFICER, UNION OF SOUTH AFRICA

Africa south of the Sahara forms a unit of countries with many common features Because of early remoteness, climate, and disease, it was until lately isolated from Europe, and so lacks written history Its peoples—Bantu, Negro, Hamite—have many common physical and social characteristics It is the Africa of the tropics and semi-tropics, with desert, jungle, heat, and sun obtrusive It has been the region of the world most affected by European colonialism It has had an evil name because of the men, especially those coming from temperate lands, who have been killed or disabled by its sicknesses

European influences were first brought to the continent by explorers, missionaries, traders, and prospectors In the 19th century the Colonial Powers, scrambling after them, launched tribal Africa into the Western way of life, and brought it precipitately into the material and technological world created by the Industrial Revolution Through the colonial agents of this world phenomenon, Africa was in time largely freed from the blight of tribal massacres, slavery, starvation, and epidemic disease

Today Africa is impatiently grasping the outward forms of sovereignty More than half her peoples will achieve political independence this year, and before the decade is well advanced the rest will almost certainly have followed Colonialism will then have vanished and new, and largely inexperienced, States will be struggling with the daunting social problems of emerging millions This fact, partly political though it may be, directly affects the future of medicine in Africa

The astonishing reduction in the amount of disease during the past 60 years has been possible because colonialism gave Africa a phase of social stability with a rising economy, and the whole paraphernalia of good central and local civil administration Western medicine had then its opportunity to prevent and cure disease "en masse"

Western ideas have moulded the form medicine has taken both in sovereign countries like the Union of South Africa and the Federation of Rhodesia and Nyasaland, as well as in the Colonial territories of Belgium, France, Portugal, and the United Kingdom In this medicine there has been a significant place for the medical missionary, the private practitioner, the medical professional association, the autonomous university with its medical school, and the public but unofficial research institution It has been a medical system constantly nourished and refreshed from the European home countries

But, though this European form of medicine has given a place to the non-governmental and the non-official, most medicine in Africa has a strong official character The hospital and clinic services of South Africa and the Federation and the general Colonial Services, despite their Western origin, are largely official and depend on Government funds for providing free or subsidised services

If the future held no other obstacles, the official nature of most of the developing African medical systems would create difficulties enough This official bias will be continued by most forms of external aid It makes uneasy those who would like to see the individual doctor and the non-official organisation claim a worthy place

Medicine, in a full sense, today only achieves results if there is an adequate community with law and order, efficient civil administration, good communications, and a sound economy In other words the good health of a community needs not only good doctors, but also well-run cities, villages, and country districts with sufficient food, pure water, efficient waste-disposal, proper housing, and all the other advantages of good government Inevitably the changing political and social scene in Africa will alter the future of medical and other public services

UNITED NATIONS AID

The New Africa is being moulded by external as well as internal forces The most important stimulus comes from the United Nations family, with the World Health Organisation as the agent responsible for health and medicine It is perhaps not fully realised how great a change is being wrought by the United Nations agencies, even though they are intergovernmental and not super-governmental organisations

Delegates from African States appear in ever-growing numbers in the councils of the world and many already have been effective office-bearers African regional and other offices already represent the U N Economic Commission for Africa, the U N Technical Assistance Administration, the Food and Agriculture Organisation, the World Health Organisation, and the U N Children's Fund Most of these directly or indirectly affect health programmes, and as a group are not insignificant in power and resources

A stream of people—consultants, technical experts, advisers, and others—are being directed by the U N group into Africa Another stream flows out carrying delegates, committee representatives, and postgraduate fellows and students

People moving in and out of Africa as part of its technical and scientific evolution are not a novelty But there is something very different about the flow sponsored by the United Nations family The volume is more impressive and it is directed to and from many more countries U N consultants and technical experts now working in Africa come not only from the United Kingdom, France, and the other colonial countries, but from North and South America, the whole of Europe, and several Asian countries The Africans travelling overseas for experience and training also visit a much wider range of countries

The technical aid in medical fields is massive It is gladly accepted by the new African States without the undue sensitivity they sometimes show to aid offered by individual foreign Governments As a result, the organisation of hospital services and clinics, and the training of doctors, nurses, and other staffs have been speeded up

A fundamental principle in this form of external technical aid is to be noted Since the United Nations system is official and intergovernmental, it works through national governmental services It is thus a force which quite properly creates and strengthens official and governmental services in the countries it helps It is supporting officialdom everywhere, and will increasingly do so in the future African medical and other services This is satisfactory provided non-governmental organisations and arrangements are not neglected

---

* Based on a lecture delivered under the auspices of the Institute for the Study of Man in Africa, Johannesburg, on June 14, 1960

OTHER INTERGOVERNMENTAL ARRANGEMENTS

The passing of direct colonial control and the arrival of United Nations technical aid do not mean that the Colonial Powers have given up all responsibility for emerging Africa They are helping in the development of such things as general administrative services, universities, hospitals, rural clinics, research institutions, water-supplies, and roads Their hope is that if the new countries have sound public services the transfer of authority to peoples who, though politically active, are on the whole administratively and technically inexperienced will be smoother

It is not only the old Colonial countries which are eager to help the New Africa The Union of South Africa has often and officially stated that it wishes to draw on its own rich technical resources to help the rest of Africa Such help has already been given in many ways

Several South African scientists have visited other African countries, some have served as consultants, a few students from other territories have been trained in the Witwatersrand, Cape Town, and Durban Universities and medical schools, some research teams have worked on general African problems, and the South African Institute for Medical Research is used by many medical services as far away as the Sahara It is also part of several international scientific networks—e g , in virus diseases, spirochætal infections, bilharziasis, malaria, and so on

However, it is doubtful if South Africa yet plays a part proportionate to her technical resources Compared with the many scientists and doctors working in the New Africa who have come from Britain, France, and other European countries, or with the hundreds of undergraduate and postgraduate African students who flock to other medical centres, South Africa seems inactive Yet unless she vigorously develops this two-way exchange of medical scientists and students, her own medicine and science may languish as an international or African force

A more recent feature of intergovernmental technical aid to Africa is the bilateral governmental system Its first great advocate was the United States of America, and Africa has benefited liberally American medical missions are important now in many African states, and there is a steady stream of African students to the great medical and public-health schools of the United States She is keen, too, to cooperate with local groups in research into the many tropical and other diseases which are still difficult to control or treat such as bilharziasis, malnutrition, and many parasitic conditions

But the American bilateral programmes are having some unexpected imitators The Communist countries are already at work in many fields, including medicine, and it is probable that the Chinese will also join in sending technical experts and attracting fellows and students from the African States

NON-GOVERNMENTAL INFLUENCES

The pioneers of Western medicine in Africa, as elsewhere, were not officials but private doctors, and the medical missionary was the pioneer of the pioneers For a hundred years these courageous and selfless people have been among the great medical and social liberators of Africa Their work, generous and independent, goes on Today it is perhaps again critical If tolerated in the new countries, these societies could be a valuable instrument in continuing the spirit and practice of personal and non-official medicine of the best type

It was earlier inevitable, in tropical and tribal Africa, for the Colonial Powers to break the shackles of epidemic and endemic disease by introducing modern medicine through official services So, with the important exceptions of the larger European communities, the private doctor has not been a force

Again, with the exception of South Africa and Southern Rhodesia, medical and nursing professional associations have had an insignificant influence on medical and health policies in Africa compared with the part they have played in Europe and America The professions are generally a sound influence on official ministries, for in considering national health problems they usually hold more than a narrow professional view They contribute wisdom and experience and usually add to the maturity of the community It is, therefore, unfortunate that strong professional associations with a backbone of independent doctors seem unlikely to develop in the newer African States

Yet, paradoxically, one of the dangers threatening medicine in Africa is the private doctor who abandons the ethical code of his profession The charlatan in Africa is already playing on the credulity of the naive and superstitious He may be witch-doctor, masquerading doctor, or qualified practitioner prostituting his calling The new States, therefore, have a clear responsibility to protect their people from exploitation But the State will not succeed in this aim without a medical profession of the highest integrity keen to keep its own house in order

Industry has also contributed to African medicine Most large industrial organisations have acknowledged their obligation to protect the health of their communities In the gold, copper, and trading industries of South Africa, the Rhodesias, the Congo, and West Africa hundreds of thousands of workers are given health and good physique and learn much about keeping themselves fit during the years of their employment Much of this knowledge diffuses into the kraals and villages Hence the position of industry in the new States is of concern to medicine If they accept that private industry can contribute to the economy, this will open a useful opportunity for non-governmental medicine

Another non-governmental agent which could do immeasurable good for medicine in the New Africa is the large philanthropic or public Foundation In Africa the Rockefeller and other American foundations have been joined by the Nuffield Foundation, whose support for the establishment of a vigorous and modern medical school in Salisbury is likely to be one of the germinal events in Central African medicine As Africa changes from colonialism, the great Foundations, both American and British, will have an opportunity of service greater than in the past They are altruistic, objective, generous, and free of politics and bureaucracy They thus can balance the help coming to Africa from the intergovernmental agencies—multilateral or bilateral—with the best type of non-governmental support It will be unfortunate if the new States are unwilling to invite the Foundations to help in the large new medical, technical, and social programmes for which they will soon be responsible

A final example of non-governmental health and medicine is the voluntary organisation In South Africa and the Rhodesias, and to a lesser extent in the Colonial Territories, such bodies have been valuable, and it is to be hoped that the New Africa will encourage the work of voluntary groups, particularly in child and maternal health, first-aid, accident prevention, and social welfare But many circumstances are against them, especially if the new States loosen their Western relationships

SOCIAL TRANSFORMATION

The New Africa to which medicine must adjust itself is as much a product of social, including economic change as of the more obvious political movements. These social changes—in such things as education, economy, agriculture, industry, science, and communications, and in religion—have been accelerated by the results of Western medicine. The reduction of pestilence, as much as the control of famine and tribal warfare and the abolition of slavery, launched the African social revolution. Now, along with the present political and nationalistic movements, these social forces are influencing the future setting for African health and medicine. Indeed the replacement of the social customs of tribal Africa, by something modelled on, or influenced by, external ideas and examples, is happening too rapidly for medicine and the other social services to keep pace. Even if these social forces are not diverted or delayed by political troubles, medicine in the New Africa will still have to face problems very different from the old.

One is already ominous—the growth of population. Released from the old checks of slavery, starvation, tribal war, and preventable disease, the annual rate of increase in some territories is already 3%. People are migrating into the towns and factories, and large urban and industrial populations may place an unbearable demand on public, including medical, services. The witch-doctor is no longer supreme. Old fears have gone, so that hospitals and clinics are being swamped, and overworked doctors and nurses are driven to exhaustion. Africa, like most other developing countries, has too many ugly and squalid towns and villages, and yet their inhabitants increase relentlessly to make slums more depressing and dangerous. Only watchful sanitary administration and good fortune seem to explain the relative absence hitherto of serious disease.

Another feature of the social transformation of importance to the medical reformer is the growing emancipation of the African women. In much of Bantu society women still lack freedom and are only slowly training as midwives, nurses, health visitors, or teachers. Sufficiently educated girls are deplorably few to meet the urgent demands of nursing and teaching.

CHANGING PATTERN OF DISEASE AND DISABILITY

Africa's reputation has not yet recovered from the casualties among those who in earlier days came to explore, trade, or fight. Portuguese missions defeated by fever, Mungo Park's expedition ending in disaster, Dutch, Danish, French, and British trading-posts on the West and East coasts enlarging their cemeteries daily, the decimation by typhoid and dysentery of the South African, and by the malaria and dysentery of the East African campaigns of the first world war—these and many more gave a sinister name to the climate and disease of Africa.

Before medical science unravelled the maze of tropical disease, the hazards of Africa seemed to lie in its malignant climate. Sun, swamp, heat, miasma—all were accused. However, recognition of the true situation has seen the dramatic conquest of most of Africa's pestilential and tropical diseases. Not only is the indigenous African population doubling itself every 30–40 years, but European families are living happily and healthily even in such dreaded areas as the West Coast and the Central African Valleys. If one of the 18th or 19th-century Europeans returned, he would perhaps be chiefly amazed by the contempt of the moderns for the huge pith helmet, red spinal pad, and abdominal or cholera belt which he considered an essential protection against the baleful African sun and climate.

Today we have gone a long way towards separating the climatic and environmental from the communicable and nutritional factors in the cause of African disease. The greatest triumphs were the discovery of the causes and methods of treatment and control of the tropical fevers. The devastating epidemic and endemic diseases of previous centuries are now cowed. Yellow fever, malaria, sleeping-sickness, smallpox, dengue, yaws, and many more are shadows of their former selves. The blame placed on tropical and African climate is now known to have been much exaggerated. Now we know that an efficient sanitary system and a good diet can make nearly all Africa tolerable and healthy.

Formerly nearly all the dangers to life lay in communicable disease carried by insects or infected food or water. Climate was indirectly responsible in that it gave these diseases the medium for their propagation. With disease reduced or eliminated, tropical climates become themselves less fearsome, if still uncomfortable. Today we know much about the direct effects of sunlight, heat, and humidity. Unpleasant though extremes of these may be, their effects can be borne more tolerably by applying the present knowledge of the human body's capacity for acclimatisation and adjustment. Much of this work was shown on the Witwatersrand—e.g., the regime of adjustment to work, environment, heat, and humidity applied in the mines. The human power of physiological adaptation, combined with modern housing and work places, and, if necessary, air-conditioning, is radically changing the medical view of the future capacity of Africa to support healthy human populations even in its more fearsome desert and jungle regions.

With the astonishing decline of the pestilences a new pattern of diseases is appearing. Some of these diseases have always existed but were overshadowed. Others seem to be truly new, or much more virulent. Others are a product of social change.

Examples of diseases now more prominent by contrast are malnutrition and some of the dysenteries. Mass famine is now rarely seen, but protein malnutrition has lately been recognised as widespread. Infantile diarrhœa persists as a serious public-health hazard.

A group of diseases partly old and previous unrecognised, and perhaps partly new or more virulent, is those caused by viruses. Besides such well-known viruses as those of poliomyelitis, influenza, and trachoma, a whole host of new agents has been found in Africa. Much of this research has been done in the South African Poliomyelitis Foundation supported by a team from the Rockefeller Foundation.

Two examples of conditions aggravated by the stresses in a society shifting from the pastoral to the modern are tuberculosis and industrial disease. Unfortunately tuberculosis is increasing in nearly all African territories, especially in the town and labouring groups. The story of industrial expansion in other continents is unhappily repeated. Again, increasingly as the New Africa becomes industrialised, the problems of disease in mines and factories will arise, especially if the vigilance of the national health and labour administrations slackens.

Modern life is not only putting people into factories and towns, it is altering the agricultural scene. More and more large-scale agriculture in Africa is dependent upon irrigation. This is spreading bilharziasis and making the control of its snail vector more difficult. Several other parasitic worm diseases and intestinal infections continue to cause much sickness and inefficiency throughout tropical areas. Their reduction must await improved sanitary services and higher personal standards of cleanliness.

In the new pattern of disease one feature is becoming more and more striking—accidents Even in remote regions of Africa accidental injuries are serious Every new road brings an almost incredible number of car and lorry fatalities and cripplings In New Africa, as in the rest of the world, the accident of the home, road, and factory is killing and maiming people and filling hospitals in ever larger numbers

As the acute diseases recede and as the chance of living longer in a modern world increases, the so-called chronic degenerative conditions obtrude themselves Here, too, Africa shows signs of copying the world design Whatever may be the full story of their causes and associations the melancholy record in more and more countries is of death and disability from heart and kidney disease, nerve degenerations, and malignant disease The mental afflictions, too, will probably be more obvious in the future Africa

WHAT PATTERN FOR MEDICINE?

The speed and confusion of events are unfavourable to prophecy, but once the transition to sovereignty is achieved and a new African political condition is created, what will be the philosophy and form of its medicine?

In an immediate technical sense there will be enormous tasks to shoulder The prospects of rewarding careers will lie before the new African doctors and nurses—suffering to be relieved, premature mortality to be challenged, fuller and healthier lives to be sought for the growing millions They will also have an enviable opportunity to probe many remaining mysteries in disease They will be the privileged observers of the whole gigantic phenomenon of a people being changed by social pressure to accept new ways of life Such tantalising questions as the effects of climate and environment on energy, mental capacity, physiological efficiency will be theirs to study Medicine in the New Africa will be rich in obligation and in opportunity for research

Public-health and preventive medical measures to meet the challenge will only be effective, indeed possible, if the general administration is competent But even assuming that no disastrous weakness appears in the public-health organisations of the New Africa, its future medical philosophy is still uncertain

Medicine at its best is something finer than an exercise of technical skill In the medicine being introduced into Africa and other developing regions this broader duty is too often neglected Yet here the need is more desperate than in the older lands where all upbringing supports understanding of such social responsibilities The culture and civilisation which have produced modern medicine, and of which it can be a noble component, are also essential in the new countries if they are to gain completely Medicine's true teachers and disciples give more to Africa than medical care in a hospital or clinic Their integrity and philosophy are a demonstration of the goodness to be found in their culture This is necessary if the struggling new African medicine is to be something more than a mere materialistic technique or rival to tribal witchcraft, which could easily revive under a cloak of African nationalism

Western medicine in helping Africa should not overlook the need for this broader interpretation of its possible service It should guide Africa to create people who are good doctors and nurses, but are also prepared to follow fearlessly the principles founded over many difficult generations in Europe and America This responsibility will be more onerous in New Africa than in the older settled communities of Europe and America But the future African doctor, by being a man of integrity and principle, will increase the stability of his country and the respect it will earn in the world

Special Articles

THE MINISTER ON THE HEALTH SERVICE

Mr Enoch Powell, Minister of Health, reviewed the structure of the National Health Service in an address to a joint meeting of the English and Welsh Executive Councils Associations at Llandudno on Oct 27 He said

> "The National Health Service, by its very nature as a comprehensive State service, holds out dangers and possibilities of harm as well as opportunities and possibilities for good We can never wholly eliminate the risks and be left with only the opportunities What we have to do is to discern as clearly as possible where those risks lurk and what they are We shall then be in the best position to counteract and minimise them"

The service was the channel through which flowed the overwhelmingly large proportion of our national income which we devoted to the care of health and the treatment of the sick The fraction so devoted had not, on average, been much larger during the last decade than it was twenty years earlier—though, of course, the national income itself had been larger and so, consequently, had been the absolute amount of resources devoted to medical care One thing was certain as our national income continued to rise, the volume of effort and resources devoted to health would rise Another thing, too, was certain—that with the inevitable changes in the texture of society and in the content of medical knowledge and theory, the nature of the resources and the application of the effort devoted to health would also alter In any given state of society and medical knowledge there was an ideal application of the available resources which would yield the greatest harvest in terms of health, wellbeing, comfort, reassurance—in short, of happiness We should never quite attain this ideal, but we ought always to be tending towards it, and success or failure in doing so depended on the nature and the functioning of the channels through which the available resources flowed Mr Powell continued

> "It is in this context that a comprehensive State service has its dangers In such a service responsibility is inevitably centralised—in the Minister answerable in Parliament Because responsibility is centralised, so, in large measure, must be decision, since responsibility implies the power to take the decisions for which one is answerable This in turn implies an administrative machine which will link all the parts together and secure conformity with the central policy and decisions Now, all this brings with it a great danger—that of rigidity Policies which are formed centrally and executed administratively are bound to be slower to change and less adaptable to alterations of circumstance and demand than if responsibility were diffused and decisions were independent The great machine is bound to have a one-track mind, to be cumbrous and unresponsive, to abhor variations, to be insensitive to the world around it
>
> "These disadvantages apply anywhere, but in the field of health and medical care they can be specially dangerous Here is a field in which it is the individual mind, the local experiment, even the chance observation, which bring about the great advances The man or woman who is (as we say) before

his time, at whom officialdom is bound to look askance, whom contemporaries treat as an oddity or a nuisance, turns out to be the pioneer, doing the work which determines the direction of future development These people need an environment in which they have opportunity, even encouragement, certainly not repression But how is the machine to know them when it sees them ?"

Not only the methods of giving medical care, but the character of the need for it were constantly changing Post-war legislation and planning for all the welfare services reflected the conditions of the pre-war world for it had nothing else to go on They were trying now to assess the revolution of the 1950s, but it might be far into the 1970s before they could adjust the machinery to take account of it This conflict between the characteristics of a comprehensive State service and the facts of social change and medical progress could never be fully resolved, for it was inherent But by recognising it, there was much they could do to limit and counteract its dangers

Those who framed and hammered out the National Health Service were not unconscious of the dangers, and they deliberately embodied in its structure elements of independence, both lay and professional, to be a counterpoise The contractual status of the general practitioners, dentists, and opticians, the separate representation of the doctors and other professions in the structure of the hospital and executive council services, the power and authority of the professional colleges and associations—these might seem to have a fine old English illogicality in a State service "But a wise Minister of Health will see in them not hindrances but safeguards to the soundness of his work, and in all that I do or seek to do I shall be as jealous of the independence of the professions as they are themselves," said Mr Powell

But all these built-in counterpoises in the structure of the National Health Service to the dangers of the great machine would not be sufficient if the great machine itself were all "The National Health Service is intended to be comprehensive, it is not in my view intended to be exclusive," went on Mr Powell "For the service's own sake, I attach the highest value to the fact that medical service and care is also available outside it and that completely independent organisations exist in the field, to support and conduct research, to study and criticise, to supplement, assist, and (why not ?) overlap the services provided by authority of Parliament" He welcomed the flexibility and spontaneity which these other channels bring to the nation's provision for health

Mr Powell recognised three trends in the modern approach to health and medical care (1) the growth of community care and aftercare of the sick, "which takes off the hospitals work which can be done more effectively and more beneficially outside them", (2) the development of preventive and remedial measures which will prevent admission to hospital or lengthy treatment there, and (3) the more intensive and efficient use of hospital accommodation, expressing itself in higher turnover of patients and lower ratio of beds to population In two of these three the initiative in development lay with the local authorities, and if the new trends were to find full expression, the biggest expansion within the health service in the next decade would have to come on the side of local government One should note finally that as the link between the three trends is, from one point of view, the patient as an individual human being, so the link from another point of view is the friend and adviser of the patient as an individual human being—namely, the general practitioner

Turning to finance, Mr Powell declared that the financial structure of the National Health Service could not have been devised more effectually if the object had been to put the three main elements into watertight, non-communicating compartments There were in fact three separate financial systems, and consequently the interrelation between developments and decisions in each of the three fields was virtually impossible to express in the clear financial terms which would so much help administration and public understanding "However, I must say bluntly that a major reform in the financial structure of the National Health Service is farther off at present than the eye of a politician can see We must work with the structure we have got, and I shall not be content until I can see a long-term picture in which the development of the hospital service is dovetailed with the development of the local-authority services, and the future function of the family practitioner is related to both"

Dialogues of Today

SOCRATES, THIS IS YOUR LIFE!

HAEMON Come in, Socrates, and don't be surprised to see so many people We know that you are becoming an author yourself for the first time, so we thought we would like to congratulate you Socrates, this is your life!

SOCRATES It is true, Haemon, that I am no longer to be dependent upon Plato and Xenophon for an account of my words, but I am no author any ideas to be found in my conversations are contributed by those with whom I talk I am only a midwife, delivering other people of their ideas

HAEMON Come in, Apollodorus, and tell us how you first met Socrates

SOCRATES Welcome Apollodorus! What have you been doing today ?

APOLLODORUS I have been in court arguing as to whether or not certain words are obscene

SOCRATES Is there any more important question ?

APOLLODORUS I should hardly have called it important, Socrates

SOCRATES But tell me, is not obscenity sometimes a kind of swearing ?

APOLLODORUS Sometimes it is

SOCRATES And when men swear do they not use words, which are held sacred, in a way which is considered blasphemous ?

APOLLODORUS Certainly

SOCRATES It would seem then that if we are to decide why words are obscene we must also consider what makes words sacred, and we can hardly do that without asking what is sacred, and why it is so So you see why I said that the nature of obscenity is a most important question But, tell me, is there any characteristic of the obscene words themselves which distinguishes them from other words ?

APOLLODORUS I don't know of any

SOCRATES Are they not all short words, usually of one syllable ?

APOLLODORUS I suppose that is true, but surely it is not the form of the word but the meaning which renders it obscene

SOCRATES Surely not, Apollodorus, for if instead of a word of four letters you use an equivalent one of four syllables, the feelings of your hearer will be quite different, although the meaning is the same Does it not seem to you that a short word contains all its energy in a small space and at high tension, and at once conveys to us a physical reality, whereas a word of four syllables carries its energy at low tension, and so conveys a meaning which is emotionally diluted, and makes far less impression on the feelings?

HAEMON Thank you Apollodorus! Now here is Analyticus

SOCRATES It is appropriate that you should have come just now Analyticus, when we are talking about obscenity, for are there not many people who think all your writings obscene, even though you use many words of more than four syllables?

ANALYTICUS Yes, indeed, Socrates, but when I am called a corrupter of youth I console myself with the fact that they call you the same.

SOCRATES Tell us why you think some words are obscene.

ANALYTICUS I think the form of the word is only one factor, important though it is A word may transmit emotion forcibly, but the emotion is related to the thing signified If some things were not sacred swearing would lose its point, but so it would if it were not considered reprehensible, and it is reprehensible only because some things are sacred. People sometimes speak of obscenity as animalism, but that is just what it is not Animals alone are innocent of obscenity Obscenity implies a sense of guilt. If you never swear you are either perfectly balanced or too conscious of your own guilt

HAEMON Here is Eryximachus

SOCRATES Welcome, Eryximachus, for there is no one more fitted than you to explain to us the nature of obscenity, since no one behaves more shamelessly than you.

ERYXIMACHUS How is that, Socrates?

SOCRATES Do you not discuss with your patients matters which they would be ashamed to talk about with anyone but a doctor, and when you examine them do you not insist that they should conceal nothing which their modesty makes them conceal from others? And in all this do either you or your patients feel any shame?

ERYXIMACHUS But there is nothing obscene in all that, Socrates, for modesty is a matter of convention and shame does not arise in the relation between doctor and patient

SOCRATES It is the same with me, for I am not only a midwife who delivers men of their ideas, I am also a physician who seeks to examine their thoughts in all their nakedness and a surgeon who practises the orthopædics of the mind And it is my aim to examine men's words and to persuade them to let them be examined in the same spirit of truth with which Eryximachus examines their bodies

HAEMON I am sure we all wish your book the success it deserves Socrates, master of words, this is

XANTHIPPE (*marching firmly into the room*) your wife! I'll give you words! Was there ever such a man? He hasn't slept for two nights, yet here he is talking about words And he drinks twice as much as anyone else without getting drunk, and sleeps out of doors wherever he finds himself, without even a blanket. But what does any of you care so long as you can get him to discuss philosophy? I'll give you a bit of philosophy Where do his words come from? Where does his life come from? Ultimately from my kitchen Think that one out, all of you! Come on, Socrates, we're going home

(*They go*)

The Widdicombe File

LXVI.—THE DIVISION OF PATHOLOGISTS

DEAR PETER,

I thought your letter* was a very sound and moderate statement of the case—as stated by a supporter of a Faculty with the Physicians Of course you were trying to be impartial, just as every decent pathologist tries to be when he rehearses the arguments, but it is just impossible. The only man who can be truly impartial is the man who does not care one way or the other, and he will not trouble to rehearse the arguments at all That presidential address which you rightly describe as statesmanlike was, I know, meant to be impartial, but to me the final section seems to emphasise the advantages of a Faculty and the disadvantages of a College

You have recited some of the arguments for and against both sides, and I would like to review some of them as a supporter of the College You quote the argument that the establishment of a College "would be a cripplingly expensive undertaking", but this is obviously untrue unless we develop delusions of grandeur and try to obtain in a few years the sort of accommodation which other colleges have taken centuries to build up The independent Faculty of Radiologists, which is doing for radiology what a College would be trying to do for pathology in its early years, is able to exist simply and economically, and so could we You quote the argument that any examination set up by the College would take many years to achieve recognition, but what is the evidence to support this view? There is after all no really satisfactory examination at present for would-be consultant clinical pathologists, and if a College of Pathologists provides a good one I can see no reason why it should not quickly become accepted

As for the College of Physicians, it is difficult to consider it as anything but what the name implies, even though I agree that it is not exclusive, and accept that out of every 100 "active Fellows" there are about 11 administrators, 9 pathologists, 6 academic pharmacologists, physiologists, or research-workers, 2 radiologists, and an obstetrician It could, of course, cease to be primarily a physician's college, but is that the wish of most physicians? I would agree that most clinical pathologists, if they had taken up any other specialty, would probably have wished to become physicians rather than surgeons or obstetricians But clinical pathologists are still not physicians except in so far as a few hæmatologists have their own patients, and although we certainly must remain *clinical* I see no reason why we should enter into closer relations with the physicians than with any other special group of doctors

"If we were all certain that we could trust the Physicians", you say, "I think few would hesitate to accept their offer" I think you miss the point This is not a matter of trust, but a matter of intelligent anticipation of the possibility that the interests of physicians may not always coincide with those of pathologists If they do, well and good, but suppose they do not? You say that "if, after an honest trial we found ourselves unable to agree with them, nothing could stop the faculty then splitting off" I think you overlook the fact that the Faculty would be a creation of the College of Physicians, not of pathologists, and it could hardly split off as a body unless the parent college chose to abolish the Faculty Are you prepared to envisage a future situation when a body of dissatisfied pathologists has to try to set up an independent college in opposition to an established faculty? Then indeed the "dissensions and bankruptcy" of which you warn us might well become a reality

---

* We printed this letter from the File on Oct 22.—ED L

Our seniors often tell us that there is no advantage to them from either course, and that they are only concerned to provide for the younger pathologists in whose hands the future lies At the same time they tend, perhaps, to ignore the experience of most of those who discuss such matters with these younger pathologists, and find that they are mostly in favour of a College The young men do not seem to be afraid of starting in a small way provided that they can feel genuinely independent and not a sort of appendage to another college Their "image" of pathology is of a subject which is of real importance in its own right and which can therefore expect its own separate and individual organisation

If we are to build surely for the future, independence is the only safe choice When I have reached retiring age, I do not want my juniors to be able to say to me "You and your colleagues made a fine mess of things in 1960 Here we are stuck in the College of Physicians where we are not really happy, but it will be very difficult to break away now If you had only made the effort to form a College it would be well established by now Did you *have* to choose the easy way? Couldn't you see just a little way in front of your noses?"

Yours,
G G

Symposium

TICK-BORNE ENCEPHALITIS VIRUSES

FROM A CORRESPONDENT

THE Institute of Virology of the Czechoslovak Academy of Sciences acted as hosts to virologists from eleven different countries during a four-day symposium last month on the biology of viruses of the tick-borne encephalitis complex The meetings were held in delightful surroundings at the House of Scientists at Smolenice, near Bratislava Representatives from almost all the major groups working on this subject were present, and the symposium provided an unusual opportunity for workers from many different disciplines to pool information and exchange ideas in a common approach In Britain, human infections with louping-ill virus do not present a serious public-health problem, but in Central Europe, Scandinavia, U S S R, and India viruses of the tick-borne encephalitis group are a serious menace The recent recognition of human infections with viruses of this group in Canada[1 2] and the U S A[3] extends the area in which these viruses are known

Dr J Casals (New York) showed how the tick-borne viruses were placed with yellow fever and some twenty other arthropod-borne viruses into the serological group B on the basis of antigenic relationships In the past, the tick-borne encephalitis viruses have been considered a homogeneous group in spite of wide differences in the disease patterns they produced in different parts of the world Dr D H Clarke (New York) showed that they could be divided into six antigenic subgroups on the basis of hæmagglutination inhibition tests with absorbed sera and by agar-gel precipitin tests The six subgroups were represented by the classical far-eastern Russian spring-summer encephalitis (R S S E), louping ill, Omsk hæmorrhagic fever, Kyasanur Forest disease,[4] Malayan tick-borne Langat virus, and Central European tick-borne encephalitis which included Czechoslovakian, Austrian, Finnish, Polish, Swedish, and Yugoslavian strains, as well as strains from European U S S R The recently described North American Powassan virus had not yet been examined by these techniques These antigenic differences were important because they explained the reported failure of R S S E vaccine to protect humans (Dr P N Bhatt, Poona) or mice (Dr L Daneš, Prague) against infection with the virus of Kyasanur Forest disease

As in other branches of virology, tissue-culture techniques were gradually replacing older methods for the titration of viruses and for the detection of neutralising antibodies The use of a plaque technique for the titration of tick-borne encephalitis viruses was described by Dr J S Porterfield (London) and was applied by Dr V Mayer, Dr J Zavadá, and Dr R Škoda (Bratislava) to Central European strains Dr Bhatt reported that chick fibroblast cultures were as satisfactory as mice for the primary isolation of Kyasanur Forest disease virus Czechoslovak workers preferred a two-stage process—primary isolation in tissue-culture cells which were later shown to be infected by virtue of their resistance to a challenge virus Neutralising antibodies were detected by a metabolic inhibition test carried out in Hela cells (Dr H Líbiková and Dr J Vilček, Bratislava), by plaque inhibition (Dr J S Porterfield, London), or by the direct inhibition of cytopathic effect in Hela cells (Dr E Molnar, Budapest) or in pig kidney cells (Dr D Málková, Dr Z Marhoul, Dr V Fraňková, and Dr V Černy, Prague)

Vaccines derived from formalinised mouse brain had been used for many years in the U S S R (Prof E N Levkovich, Moscow, Prof A A Smorodinstev, and Dr V I Ilyenko, Leningrad) and formalin-inactivated louping-ill vaccine had been used to protect laboratory personnel (Dr D G ff Edward, Beckenham) and domestic animals (Dr D Blascovic and others, Bratislava) Attempts at producing a vaccine from virus grown in tissue culture were reported from Prague (Dr R Benda and Dr Danes), from Budapest (Dr E Molnar), and from the U S S R The major difficulty was to guarantee complete destruction of infectivity without at the same time reducing the antigenicity of the vaccine There were many parallels with the poliomyelitis vaccine problems A further important factor reported by Dr G D Zasukhina (Moscow) was that virus grown in tissue culture with a deficient medium was less antigenic than virus grown in a rich medium

The maintenance of the tick-borne viruses in Nature is still not completely understood The course of infection in an experimental animal, the laboratory mouse, was studied by Dr P Albrecht (Bratislava) in an elegant series of experiments based on the use of fluorescent antibody techniques Other animals which may be infected in Nature include bats and lizards (Dr J Rehácèk, Dr J Nosek, and Dr M Grešiková, Bratislava), domestic ducks (Dr E Ernek, Bratislava), and coots (Prof H A E van Tongeren, Leiden) Much remains to be learned about the natural history of this group of viruses Although the great majority of infections are transmitted by the bites of infected ticks, mechanical transmission by mosquitoes (Dr Z Zotowski and Dr Z Wroblewska-Mularczykowa, Warsaw) or fleas (Dr K Heyberger, Dr A Smetana, and Dr B Rosicky, Prague) may play some small part in the local spread of infection, and infection by the ingestion of milk from infected goats, sheep, and cattle is now well established The many factors which influence the natural history of viruses of the tick-borne encephalitis complex were ably reviewed by Dr T H Work (New York)

The full proceedings of the symposium will be published by the printing house of the Czechoslovak Academy of Sciences and this volume will be an authoritative summary of all present knowledge of this important group of viruses The organisers are to be congratulated on calling together the participants and drawing forth such a full and lively exchange of ideas

In England Now

A Running Commentary by Peripatetic Correspondents

ATHEROSCLEROSIS among senior consultants is to be expected nd, within reasonable limits, is perhaps right and proper ut when it strikes among your contemporaries—chaps you were at school with—complacency is shattered. So I bought a icycle, for has it not been clearly shown by the work of whoever it was that exercise and coronaries were negatively orrelated? Admittedly the idea was not entirely my own. Not long ago I chanced on a visiting physician of some eminnce, washing himself down in the hospital cloakroom. He xplained that he had just pedalled over from Fulham, a good ourteen miles away.

Choice of velocipede was easier than I expected, for there was nly one secondhand machine of my size, and when the handlebars had been changed (the old ones scraped the ground) was left with a good bargain. My early experience was alutary. 14 years of motoring had involved different (if any) muscles and the saddle impinged on areas of my big-end which I had long forgotten. Life on the roads as a glorified pedestrian seemed very different from the world of motorists, and it was most unnatural to have to stop at red lights. But I persevered and rode daily to and from hospital. As my reflexes, quadriceps, and some callosities developed appropriately, travelling suddenly became much more interesting. Territory I had motored over a thousand times yielded unnoticed gems of architecture or nuances of gradient. The prevailing wind started to play a part in my life. I turned again to Nature and the basic things of life without which a man's spiritual development cannot take place—such as irritable little dogs, midges, and rain down the back of your neck. Also you get a closer look at blondes in the bus queue. Even securing the aid of a bicycle shop was a new experience, no garage has charged me as little as 2*s* for anything.

Yes, cycling has reopened a dimension in my life. Surprising what a few miles a day will do. My weight is down, muscles are up, wind is longer, mind clearer, and waist more waisted. It has been a wonderful week to recall, as I drive to my hospital with the heater on, listening to the radio.

* * *

The Comet journey to New York was a revelation in quietness, and in the extraordinary deep blue of the sky at 40,000 ft.

Lima to La Paz was more spectacular than I had imagined. After 500 miles of Peruvian desert, with the snowcapped Andes visible from 100 miles away, we went 200 miles east at 18,000 ft, just clearing the pass between the peaks. The main impression is the extraordinary colour. Over Peru it was an orange brown, with the river beds looking like skeletons of leaves pressed in grandmother's book. Then came a range of colours like those seen near the waste heaps of a chemical works, with greens and blues and greys and yellows. But since there is the largest deposit of minerals in the world here, perhaps it is no wonder. The magnitude of the scenery surpasses anything I saw in Tibet, though perhaps that's not quite fair since I've travelled more here. But in an hour or so we went by jeep past snow-covered llamas in the frosty morning, down a series of hair-pin bends dug out of a mountainside at 10° to the vertical at times, until we came to a deep valley with bananas and apples and oranges growing. Every half mile or so there are little crosses to mark a too enthusiastic driver, because there are no walls or edges to the road.

* * *

The practice of medicine in a foreign country is full of unexpected little quandaries and hazards. It's a commonplace that one's knowledge of anatomy dwindles rapidly from the day of passing the M.B., but it's not until you have to ask someone in a detailed way about their symptoms in a foreign language that you fully realise how many parts the body has. And different languages imply, so often, different points of view, for instance, we are taught in school that *s'asseoir* means *to sit down*, yet if your patient is lying flat and you want him to sit up you say *asseyez-vous*. Again, the French do not make quite the same distinction in their language as we do in ours between pain and grief, *douleur* means both. Somewhere since Malory wrote about the dolorous wounds of Arthur's knights, we have apparently forgotten that grief may be the real trouble underlying a patient's complaints of pain. Perhaps the trickiest problem one encounters in examining a patient abroad is that of vocal fremitus in the chest. Each of us solves this in his own way and one musn't be too rigid about it all. It would perhaps be a mistake to carry too far the customs of the Old Country into Basutoland where, I'm told, the word for 99 is Machoumearobilengmonoolemongametsoarobilengmonoolemong.

* * *

Reading the remarks of my colleague, lately of Lambeth, about the neighbours who persisted in addressing him as "Mister", I wondered whether he invariably refers to himself as "Doctor". Outside working hours I reserve it for certain well-defined occasions. One of these is when making appointments at the hairdressers. There by suggesting that I am terribly busy and liable to be called away at any moment, it facilitates excuses for missed appointments and enables me to get a quick shampoo and set at short notice. Again, I always use the title when I am asked to sign my name and address on the back of cheques, under these circumstances any extra evidence of respectability is of great help.

Lately it saved me from a good deal of inconvenience. My scooter was stolen from a part of London many miles from where I live. Late the same evening, the police rang to say that they had found it, and would I come to the station at once to collect it and sign the charge-sheet. Grateful but weary, I said that I would be there as soon as possible in view of the distance and the hour. "You wait there, Doctor, and we'll send a car," the station officer assured me, doubtless with the idea that at any moment I might be called upon to save a life, and the car duly arrived.

There are times, of course, when I deliberately avoid the title, but my landlady disapproves strongly of any attempts at dissimulation. If people ask for me on the phone as "Miss ——" or use my Christian name, I hear her answer sternly, "I'll see if The Doctor is in."

* * *

Comparative textual criticism can be fun. Study of Baedeker's post-war (1958) guide to Austria and the 1929 edition provides a revealing gombarison—sorry, comparison. Though the familiar red cover with gold lettering is retained, it is no longer teutonically tubby but svelte. It contains 294 pages compared to 518, 100 of which were devoted to "Budapest, Prague and the north Bohemian spas", now omitted. (Though Hungary and Czechoslovakia had been independent countries for ten years, one would hardly gather it from the 1929 edition.) The present edition, now called an autoguide, is streamlined in other ways besides format: for instance, we no longer have blow-by-blow accounts of museums and picture-galleries with exhibits thought worthy of notice by Herr Karl mentioned in each room. There is less ancient history and esoteric information: thus we are no longer told that the Dragon Fountain or Lindwurmbrunnen in Klagenfurt is made of "chorite schist" but I was glad to see that the tablet commemorating Emanuel Hermann (1839–1902), "who invented the postcard", is still mentioned. Nor are there detailed tours of each town, starting from the railway station, but much clearer plans with "sight-seeing tours" and "through routes". In fact, modern travel is clearly no longer designed either to broaden the mind or flatten the feet. But nostalgia is catered for by the occasional survival of some of the classical phrases such as "Gasthof Lukashof, plain but well spoken of", still recalling one's aunt or members of the Women's Institute.

* * *

O, my Luve's like a red, red rose.
I hope it's nothing catching.

faculty ? Then indeed the " dissensions and bankruptcy " of which you warn us might well become a reality

Our seniors often tell us that there is no advantage to them from either course, and that they are only concerned to provide for the younger pathologists in whose hands the future lies At the same time they tend, perhaps, to ignore the experience of most of those who discuss such matters with these younger pathologists, and find that they are mostly in favour of a College The young men do not seem to be afraid of starting in a small way provided that they can feel genuinely independent and not a sort of appendage to another college Their " image " of pathology is of a subject which is of real importance in its own right and which can therefore expect its own separate and individual organisation

If we are to build surely for the future, independence is the only safe choice When I have reached retiring age, I do not want my juniors to be able to say to me " You and your colleagues made a fine mess of things in 1960 Here we are stuck in the College of Physicians where we are not really happy, but it will be very difficult to break away now If you had only made the effort to form a College it would be well established by now Did you *have* to choose the easy way? Couldn't you see just a little way in front of your noses ?"

Yours,
G G

Symposium

TICK-BORNE ENCEPHALITIS VIRUSES

FROM A CORRESPONDENT

THE Institute of Virology of the Czechoslovak Academy of Sciences acted as hosts to virologists from eleven different countries during a four-day symposium last month on the biology of viruses of the tick-borne encephalitis complex The meetings were held in delightful surroundings at the House of Scientists at Smolenice, near Bratislava Representatives from almost all the major groups working on this subject were present, and the symposium provided an unusual opportunity for workers from many different disciplines to pool information and exchange ideas in a common approach In Britain, human infections with louping-ill virus do not present a serious public-health problem, but in Central Europe, Scandinavia, U S S R, and India viruses of the tick-borne encephalitis group are a serious menace The recent recognition of human infections with viruses of this group in Canada[1 2] and the U S A[3] extends the area in which these viruses are known

Dr J Casals (New York) showed how the tick-borne viruses were placed with yellow fever and some twenty other arthropod-borne viruses into the serological group B on the basis of antigenic relationships In the past, the tick-borne encephalitis viruses have been considered a homogeneous group in spite of wide differences in the disease patterns they produced in different parts of the world Dr D H Clarke (New York) showed that they could be divided into six antigenic subgroups on the basis of hæmagglutination inhibition tests with absorbed sera and by agar-gel precipitin tests The six subgroups were represented by the classical far-eastern Russian spring-summer encephalitis (R S S E), louping ill, Omsk hæmorrhagic fever, Kyasanur Forest disease,[4] Malayan tick-borne Langat virus, and Central European tick-borne encephalitis which included Czechoslovakian, Austrian, Finnish, Polish, Swedish, and Yugoslavian strains, as well as strains from European U S S R The recently described North American Powassan virus had not yet been examined by these techniques These antigenic differences were important because they explained the reported failure of R S S E vaccine to protect humans (Dr P N Bhatt, Poona) or mice (Dr L Daneš, Prague) against infection with the virus of Kyasanur Forest disease

As in other branches of virology, tissue-culture techniques were gradually replacing older methods for the titration of viruses and for the detection of neutralising antibodies The use of a plaque technique for the titration of tick-borne encephalitis viruses was described by Dr J S Porterfield (London) and was applied by Dr V Mayer, Dr J Zavadá, and Dr R Skoda (Bratislava) to Central European strains Dr Bhatt reported that chick fibroblast cultures were as satisfactory as mice for the primary isolation of Kyasanur Forest disease virus Czechoslovak workers preferred a two-stage process—primary isolation in tissue-culture cells which were later shown to be infected by virtue of their resistance to a challenge virus Neutralising antibodies were detected by a metabolic inhibition test carried out in Hela cells (Dr H Líbiková and Dr J Vilček, Bratislava), by plaque inhibition (Dr J S Porterfield, London), or by the direct inhibition of cytopathic effect in Hela cells (Dr E Molnar, Budapest) or in pig kidney cells (Dr D Málková, Dr Z Marhoul, Dr V Fraňková, and Dr V Černy, Prague)

Vaccines derived from formalinised mouse brain had been used for many years in the U S S R (Prof E N Levkovich, Moscow, Prof A A Smorodinstev, and Dr V I Ilyenko, Leningrad) and formalin-inactivated louping-ill vaccine had been used to protect laboratory personnel (Dr D G ff Edward, Beckenham) and domestic animals (Dr D Blascovič and others, Bratislava) Attempts at producing a vaccine from virus grown in tissue culture were reported from Prague (Dr R Benda and Dr Danes), from Budapest (Dr E Molnar), and from the U S S R The major difficulty was to guarantee complete destruction of infectivity without at the same time reducing the antigenicity of the vaccine There were many parallels with the poliomyelitis vaccine problems A further important factor reported by Dr G D Zasukhina (Moscow) was that virus grown in tissue culture with a deficient medium was less antigenic than virus grown in a rich medium

The maintenance of the tick-borne viruses in Nature is still not completely understood The course of infection in an experimental animal, the laboratory mouse, was studied by Dr P Albrecht (Bratislava) in an elegant series of experiments based on the use of fluorescent antibody techniques Other animals which may be infected in Nature include bats and lizards (Dr J Řeháček, Dr J Nosek, and Dr M Grešiková, Bratislava), domestic ducks (Dr E Ernek, Bratislava), and coots (Prof H A E van Tongeren, Leiden) Much remains to be learned about the natural history of this group of viruses Although the great majority of infections are transmitted by the bites of infected ticks, mechanical transmission by mosquitoes (Dr Z Zotowski and Dr Z Wroblewska-Mularczykowa, Warsaw) or fleas (Dr K Heyberger, Dr A Smetana, and Dr B Rosický, Prague) may play some small part in the local spread of infection, and infection by the ingestion of milk from infected goats, sheep, and cattle is now well established The many factors which influence the natural history of viruses of the tick-borne encephalitis complex were ably reviewed by Dr T H Work (New York)

The full proceedings of the symposium will be published by the printing house of the Czechoslovak Academy of Sciences and this volume will be an authoritative summary of all present knowledge of this important group of viruses The organisers are to be congratulated on calling together the participants and drawing forth such a full and lively exchange of ideas

In England Now

A Running Commentary by Peripatetic Correspondents

ATHEROSCLEROSIS among senior consultants is to be expected and, within reasonable limits, is perhaps right and proper But when it strikes among your contemporaries—chaps you were at school with—complacency is shattered. So I bought a bicycle, for has it not been clearly shown by the work of whoever it was that exercise and coronaries were negatively correlated? Admittedly the idea was not entirely my own Not long ago I chanced on a visiting physician of some eminence, washing himself down in the hospital cloakroom He explained that he had just pedalled over from Fulham, a good fourteen miles away

Choice of velocipede was easier than I expected, for there was only one secondhand machine of my size, and when the handlebars had been changed (the old ones scraped the ground) I was left with a good bargain My early experience was salutary 14 years of motoring had involved different (if any) muscles and the saddle impinged on areas of my big-end which I had long forgotten Life on the roads as a glorified pedestrian seemed very different from the world of motorists, and it was most unnatural to have to stop at red lights But I persevered and rode daily to and from hospital As my reflexes, quadriceps, and some callosities developed appropriately, travelling suddenly became much more interesting Territory I had motored over a thousand times yielded unnoticed gems of architecture or nuances of gradient The prevailing wind started to play a part in my life I turned again to Nature and the basic things of life without which a man's spiritual development cannot take place—such as irritable little dogs, midges, and rain down the back of your neck Also you get a closer look at blondes in the bus queue Even securing the aid of a bicycle shop was a new experience, no garage has charged me as little as 2s for anything

Yes, cycling has reopened a dimension in my life Surprising what a few miles a day will do My weight is down, muscles are up, wind is longer, mind clearer, and waist more waisted. It has been a wonderful week to recall, as I drive to my hospital with the heater on, listening to the radio

* * *

The Comet journey to New York was a revelation in quietness, and in the extraordinary deep blue of the sky at 40,000 ft

Lima to La Paz was more spectacular than I had imagined After 500 miles of Peruvian desert, with the snowcapped Andes visible from 100 miles away, we went 200 miles east at 18,000 ft, just clearing the pass between the peaks The main impression is the extraordinary colour Over Peru it was an orange brown, with the river beds looking like skeletons of leaves pressed in grandmother's book. Then came a range of colours like those seen near the waste heaps of a chemical works, with greens and blues and greys and yellows But since there is the largest deposit of minerals in the world here, perhaps it is no wonder The magnitude of the scenery surpasses anything I saw in Tibet, though perhaps that's not quite fair since I've travelled more here But in an hour or so we went by jeep past snow-covered llamas in the frosty morning, down a series of hair-pin bends dug out of a mountainside at 10° to the vertical at times, until we came to a deep valley with bananas and apples and oranges growing Every half mile or so there are little crosses to mark a too enthusiastic driver, because there are no walls or edges to the road

* * *

The practice of medicine in a foreign country is full of unexpected little quandaries and hazards It's a commonplace that one's knowledge of anatomy dwindles rapidly from the day of passing the M B, but it's not until you have to ask someone in a detailed way about their symptoms in a foreign language that you fully realise how many parts the body has And different languages imply, so often, different points of view, for instance, we are taught in school that *s'asseoir* means *to sit down*, yet if your patient is lying flat and you want him to sit up you say *asseyez-vous* Again, the French do not make quite the same distinction in their language as we do in ours between pain and grief, *douleur* means both Somewhere since Malory wrote about the dolorous wounds of Arthur's knights, we have apparently forgotten that grief may be the real trouble underlying a patient's complaints of pain Perhaps the trickiest problem one encounters in examining a patient abroad is that of vocal fremitus in the chest Each of us solves this in his own way and one musn't be too rigid about it all It would perhaps be a mistake to carry too far the customs of the Old Country into Basutoland where, I'm told, the word for 99 is Machoumearobilengmonoolemongametsoarobilengmonoolemong

O, my Luve's like a red, red rose.
I hope it's nothing catching.

Letters to the Editor

FUTURE ORGANISATION OF PATHOLOGISTS

SIR,—A voting paper is about to be circulated to pathologists asking them to record their opinion for or against a division of pathology within the Royal College of Physicians, or a new College of Pathology

We have for many years been concerned with research in pathology and with the training of pathologists, and believe that a higher examination based on a background of suitable training is essential to ensure that candidates either for hospital or academic appointments have acquired a reasonable grounding in their subject

We both write as past presidents of the Association of Clinical Pathologists, who have been openly critical of the procrastination of the Royal College, but who are satisfied that the suggestions now put forward by it are what is required Undoubtedly, the Royal College has been unduly tardy in making any suggestions, but the present generous and unequivocal terms make amends

It is generally agreed that in modern conditions the membership is an unsuitable examination for pathologists In the time available the techniques of clinical examination and of pathology cannot both be mastered

We welcome the opportunity of still closer cooperation with our clinical colleagues Not only are they progressively more dependent on us for confirmation of diagnosis, or indeed in many cases for provision of all the important data, but, reciprocally, we also are dependent on their acumen and powers of selection for our daily interests

We have long believed that what is needed is

(1) A higher qualification of the same status as the M R C P and F R C S

(2) An academic centre which would uphold the standards of pathology and help in maintaining good standards of training in pathologists

(3) A body to speak for pathologists

In our opinion the suggestion of the Royal College satisfies these requirements We believe that unless this opportunity is accepted there will be a very long delay before we realise our ambitions

London

JOAN TAYLOR
R J V PULVERTAFT

SIR,—Much has been said and written on this subject by the more learned and senior practitioners of our specialty, but little by the juniors As one of their number may I put forward three points

The primary reason for any alteration in the present position is to ensure recognition of the status of pathologists, despite the fact that a man's status depends above all upon his personality and the quality of his work, and only secondarily upon his qualifications Higher qualifications, however, are necessary to prove adequate training in one's own specialty for promotion to consultant or similar grade, and the institution of a specialist examination in pathology, of the highest standard, is now urgently required To the pathologist in training it is the most important facet of the present discussions The expenditure of time and work by those who aspire to the membership of one of the Royal Colleges of Physicians has been eloquently described by Professor Cappell in his presidential address [1] to the Association of Clinical Pathologists It is certain that only the qualification offered by the Royal College of Physicians will have the immediate high standing required to divert them from such examinations

The finances of the new organisation are of particular interest to impecunious registrars and lecturers It has been said that the provision and maintenance of any reasonable building will cost each member an initial donation of about £100 and an annual subscription of up to £25! Some of us may not be able to find such a sum Are we to be excluded from the college until we are senior enough to afford the subscription, and if so will we ever achieve the seniority? However, we are assured that industry and various benevolent foundations will provide the necessary funds Even if the money is forthcoming, I do not believe we can justify spending such vast sums on establishing a college, when there are so many research projects urgently needing finance Would our money not be better spent on research on acute leukæmia in children or even coronary disease in pathologists than upon a building? £100,000 would buy a lot of knowledge of disease—could we not devote our benefactions (if any) to establishing a series of research fellowships rather than a college?

If a College of Pathology is to be founded then I believe it must be as broadly based as possible and must be open freely to all those who work in and around the subject, scientist or doctor, whether academic or clinical Pathology is neither practised nor advanced solely by those on the Medical Register However, in a Faculty of the Royal College of Physicians it would be logical to restrict full membership to the medically qualified

The College of Physicians of London is a body of the highest standing and to be called a physician is no dishonour I hope, with Peter Davey,[2] that a Faculty will be established They offer us more than does an independent college in the foreseeable future, and at less cost The generosity of their terms puts us in an immensely strong position, and we can always withdraw

Finally, may I suggest abandonment of the term " Division of Pathology ", for the words come uncomfortably close to the truth

London, S W 15 P O'GORMAN

*** Another view on this subject is given on p 1025 in a letter from the Widdicombe File —ED L

ATHEROSCLEROSIS AND CORONARY HEART-DISEASE

SIR,—Surely your correspondents are arguing on points of semantics rather than pathology As you, Sir, rightly pointed out last year,[3] patients do not suffer or die from coronary disease, but from the consequences of myocardial ischæmia, which may be acute, chronic, or spasmodic I have always held that one of the best classifications of disease causation, is that which we learned at our obstetrician's knee, of which a part ran—faults in the powers, faults in the passages, faults in the passenger Myocardial ischæmia may be due to faults in the power of the heart's action, faults in the coronary passages whether narrowed or occluded by what you will, or faults in the passenger—the blood, which may be deficient in oxygen-carrying capacity, or contain a substance noxious to the myocardium

In spite of the welter of investigations on atheroma and degenerative heart-disease, we remain remarkably ignorant as to the frequency, degree, and type of myocardial ischæmic change to be found at death in the population as a whole, and without this many of our deductions in this field are insecure I believe that a study, almost completed here by Dr C J Schwartz and Dr J R A Mitchell, will give us this information, as far as the current Oxford postmortem population is concerned, and may encourage others to carry out comparable investigations elsewhere

---

[1] *Lancet*, Oct 15 1960, p 863

[2] See *ibid* Oct 22 1960, p 921

[3] *Lancet* 1959 ii, 863

No-one would dispute that one may find coronary narrowing or occlusion in hearts from persons of all ages, yet it remains that in a high proportion of elderly persons, ischæmic myocardial lesions occur, which are quite different in character from those usually seen in the younger age-groups, for example, there is the condition which Linzbach called reticular myocardial necrosis, but unhappily this is a sphere of cardiac pathology which to a large extent is unexplored

Turning to the Registrar-General's statistics, we find some curious features

England and Wales Crude Death rate to a million living

	1940	*1949*	*1958*
Arteriosclerotic heart-disease, including coronary disease (I S C. 420)	573	1093	1863
Myocardial degeneration with arteriosclerosis (I S C. 442 1)	467	617	532
Other myocardial degeneration (I.S C 422 2)	1548	1274	656
Total degenerative heart-disease (I.S C. 420 – 442 1 2	2588	2984	3051

As everyone knows, the death-rate attributed to "arteriosclerotic heart-disease and coronary disease" has increased more than threefold in the past eighteen years, but "myocardial degeneration with arteriosclerosis" has hardly changed at all and "other myocardial degeneration" has fallen to a third, so that if one groups together the rubrics that can be regarded as representing ischæmic heart-disease (I S C 420, 422 1, 422 2), the rate has only increased by a fifth, which is little more than is to be anticipated in view of the increased expectation of life I am, of course, as aware of the defects of comparison of crude death-rates as against standardised mortality ratios, as I am of the answer which John Graunt found to his question, why there were so few deaths attributed to the Pox in the Bills of Mortality Nevertheless, it might be worth while, for those who believe, that by feeding rabbits or men on unnatural diets, they will determine what factors in modern life have caused this spectacular increase in deaths attributed to "coronary disease', to try and find out what are the factors which have caused the almost equally spectacular decrease in deaths attributed to "myocardial degeneration"

When we look at the age-differences, the Registrar-General's tables reveal another curious feature

England and Wales Age differences

	Proportion of Deaths Over 65			*No of Deaths 1958*		
	1940	*1949*	*1958*	*<65 yr*	*65+ yr*	*Total*
All causes	53%	63%	68%			
Arteriosclerotic heart-disease including coronary disease (I S C. 420)	55%	65%	69%	25 962	58,079	84,041
Myocardial degeneration (I.S C. 422)	85%	90%	95%	2195	51 577	53 772

As is to be expected in an ageing population, the proportion of all deaths occurring over 65 is steadily rising, in 1940 it was 53% and in 1958 68%, and the proportions of deaths attributed to arteriosclerotic heart and coronary disease is almost identical (1940 55%, 1958 69%), but of the deaths attributed to myocardial degeneration, 85% occurred at 65 and over, in 1940 and 95% in 1958

Putting this in another way, in 1958 there were 138,000 deaths attributed to "arteriosclerotic heart and coronary disease" and "myocardial degeneration", of which only 20% occurred under the age of 65 Of these 28,000 deaths under 65, 94% were attributed to arteriosclerotic heart and coronary disease, whereas of the 110,000 deaths over 65, 47% were attributed to myocardial degeneration

There are clearly a number of explanations for this difference, but it must be assumed that certifying doctors consider that there is a fatal form of heart-disease which they designate as "myocardial degeneration" or any of the other inclusion terms in rubric 422, which occurs almost exclusively in persons of 65 and over, and accounts for nearly half of the cases of degenerative heart-disease in this higher age-group

Naturally we have no idea what, if any, are the clinical differences or morbid anatomical lesions in cases attributed to these two rubrics but if there are real differences, other than the whims of nomenclature of the certifying doctors, then it would be in keeping with Dr Acheson's[4] observations

A H T ROBB-SMITH

SARCOIDOSIS TREATED WITH CHLOROQUINE

SIR,—I have read with interest Dr Soderstrom's article of Oct 29 in which he described the response of two patients with sarcoidosis to mepacrine He suggested that chloroquine may be used instead of mepacrine

I have treated with chloroquine systemic lupus erythematosus, periarteritis nodosa, Stevens-Johnson syndrome, and other hypersensitivity states since 1953 and rheumatoid arthritis since 1954[5 6]

The ætiology of sarcoidosis is still unproven, but there is a fairly strong suggestion that hypersensitivity may again play a part Michael[7] and Cummings,[8] for instance, related sarcoidosis to the chemical constituents of pine pollen

On the assumption that sarcoidosis represented a hypersensitivity state I have treated two cases with chloroquine since 1957

A married woman, aged 32, was first diagnosed as sarcoidosis, involving mainly the lungs, in 1956 when treatment was started with chloroquine sulphate 200 mg t d s This was continued for six months when it was stopped because of pregnancy By then all lung lesions had cleared Her condition was reviewed in 1957 and 1958, when she was quite well and the X-ray films showed clear lung fields

A married woman of 23 was first seen in July, 1957, when she had characteristic sarcoid lesions on her upper arms, trunk, and buttocks, and hilar-gland enlargement Biopsy confirmed the clinical diagnosis The Mantoux test was negative Chloroquine sulphate 200 mg t d s was started in July, 1957 In September, 1957, the hilar enlargement had greatly diminished and the skin lesions subsided In February, 1959, she was entirely symptomless and stopped chloroquine on her own By May, 1959, there was a recurrence of lesions on the right side of her cheek, upper arms, and buttock Chloroquine was immediately re-started, and by July, 1960, the skin lesions had almost completely disappeared and she felt well This patient is still on 200 mg chloroquine sulphate daily

At the international conference on sarcoidosis in Washington, D C , this year several speakers described the beneficial effect of chloroquine in sarcoidosis

Evaluation of any drug for sarcoidosis is difficult because of the fluctuation in the natural history of the disease with frequent spontaneous remissions This was the reason for not publishing my own limited experience of the drug in sarcoidosis If, however, since it appears that more widespread trials of chloroquine in the management of sarcoidosis are carried out in other parts of the world, then even a very limited trial such as Dr Soderstrom's and my own should be made known It is of particular interest that Dr Soderstrom noted selective staining of sarcoid lesions by the antimalarial There is reason to believe that chloroquine, too, has a selective action on the joints in rheumatoid arthritis, as we have found after 18 months' experience with chloroquine injections into rheumatoid arthritic joints (details are about to be published)

HEATSTROKE

SIR,—I must congratulate you on your editorial of Oct 15 Such is the reputation of your journal, however, that unless I take issue with you on a matter of emphasis it may appear that treatment in a special room with refrigerated water, as described by Guthrie and McCraken,[1] is the best and only satisfactory method of treatment I know that special rooms of this nature are provided in the Persian Gulf—but many a heatstroke has been treated successfully with only the minimum of facilities I feel that it would be better to emphasise the principles of treatment rather than the accessories, which are expensive

At the moment there appear to be two schools of thought on treatment one uses refrigerated water or iced baths or iced sheets and the other artificial sweat and forced air movement I am a convert to the second school ever since I encountered shivering as a response to treatment with iced sheets in a patient who was still hyperpyrexial After this I began to reconsider the physics of reducing body temperature

Everyone knows that during treatment it is important not to reduce the temperature to normal limits as this may give rise to shock, and if shock occurs it is very difficult to treat Immersion in an iced bath can be very "shocking" to even a normal individual just jump naked into the Serpentine next January if you wish to contest this point! Immersion in, or spraying with, refrigerated water coils the body by conduction alone and is associated, sooner or later as the body cools, with peripheral vasoconstriction This vasoconstriction converts the skin, with its superficial fat, into a fairly useful insulating layer

Heatstroke is related to cessation of sweating however caused Evaporation of sweat from the skin, by virtue of the latent heat necessary to effect this, rapidly cools the blood flowing through the dilated skin vessels, which then act as a heat exchanger to the internal organs When sweating has ceased it is logical to provide artificial sweat in the form of tepid water and to aid evaporation with strong air movement In hot climates a powerful fan and tepid water are almost universally available, and it is usually possible soon to accelerate cerebral cooling with an ice bag, or even ice wrapped in a towel, applied to the head

I have no wish to decry the work of anyone who uses refrigerated water or iced baths, because I feel that in their experienced hands this form of treatment is both successful and safe To the average doctor, however, heatstroke is a comparatively uncommon emergency and treatment must be given at once with facilities readily available I can assure you that it is perfectly possible to treat successfully hyperpyrexia of any ætiology by sponging with *tepid water and a strong air blast from a fan, even in* conditions of high relative humidity and high ambient temperature

Tropical Medicine,
Halton Aylesbury Bucks

R MORTIMER

SIR,—Your leader is very valuable Hyperthermia (as we used to call it) will follow the treatment of patients with malaria, sandfly fever, enteric fever, and influenza in uncooled hospital wards Cardiac failure is uncommon in hyperthermia, except when the condition has persisted untreated for some hours

Servicemen have been known to report sick, with pyrexia, and been sent back to their quarters, and found hyperthermic and unconscious some hours later, in such cases cardiac failure is not uncommon and the response to the most enlightened treatment is disappointing

As you say, proper application of the principles of prevention, which are well known, should be everywhere applied, especially in Service communities, and devices for effective cooling should be at hand in all situations where heatstroke is known to occur I emphasised this in 1937 [1]

St Margaret's Hospital,
Epping

FRANK MARSH

SPONTANEOUS FRACTURE OF THE FIBULA

SIR,—Dr Hobbs (Oct 22) raises an interesting point when he states that in fatigue fractures of the fibula no adequate explanation of their occurrence has been given

These fractures occur in two main groups (1) the young and athletic and (2) the middle-aged and tired The case described clearly is of the second type Fatigue in bone may be compared in some respects to that in other materials such as metal When a metal column is subjected to repeated eccentric loadings, alternating tensile and compressive strains occur and eventually lead to a fatigue or stress fracture This also happens experimentally in bone Gaynor Evans [2] reported on subjecting a piece of fibula to repeated cyclical loadings at 5000 lb per square inch, and after 3,000,000 such loadings fatigue fractures occurred

In life, however, bone has a built-in capacity to repair by osteoblastic action and only when the stimuli are repeated sufficiently within the time taken to repair is a fatigue fracture liable to occur This period is likely to be prolonged in the middle-aged Even then, if aching causes the activity to cease, the early fracture may pass unrecognised

Windsor

ROY MAUDSLEY

POLIOVIRUS-NEUTRALISING ANTIBODIES IN STOOLS

SIR,—Dr Godtfredsen's letter of Aug 13 reported failure to demonstrate poliovirus-neutralising antibody in the stools of 13 convalescent individuals We appreciate being informed of these results and hope that she and others will not cease efforts to determine the nature of resistance of the human alimentary tract to poliovirus following infection with wild polioviruses or the feeding of attenuated living poliovirus vaccines Such alimentary resistance does not accompany Salk vaccination

Our communication [3] reported the demonstration of specific antibody in the stools of 13 children recovering from poliomyelitis Actually this represented only the positive results, the tests were performed in 93 convalescing patients and *only* 13 individuals were positive Once a given stool is demonstrated to contain type-specific poliovirus antibody, the observation can be repeated and appreciable loss of titre through storage and re-thawing has not been observed The serotype of antibody observed in our 13 positive children were 5 for type 1, 3 for type 2, 4 for type 3 One child's specimens neutralised types 1 and 2 When antibody was found in the stools the same type (and of course one or both remaining types) of antibody was found in the serum As we pointed out, the stool antibody when found was always *heterotypic* to the infecting virus, suggesting that those individuals' alimentary tracts had had previous exposure(s) to poliovirus

Deviations in Dr Godtfredsen's technique from ours include our use of a suspended-cell technique, which has advantages in demonstrating "low-avidity" antibody, and our use of 0 25 ml of the stools tested instead of 0 1 ml

---

[1] Guthrie J, McCraken, A V *Lancet*, 1960, i, 682

[1] British Encyclopædia of Medical Practice vol vi, p 396 London 1937
[2] Gaynor Evans, F Stress and Strain in Bone Springfield, Ill, 1957
[3] *Lancet* 1959, ii, 272

Whether the test details per se are important is uncertain, but more children may need testing our record of 13 of 93 individuals (± 14%) suggests this Failure to demonstrate in vitro neutralising antibody of the usual kind in the stools of the remaining 80 patients may be purely technical or may have fundamental explanations The age of patient, time of stool-collections after the current infection, previous alimentary contact with the other serotypes of poliovirus, the " secretor " status of the patient's alimentary tract, and other factors may influence the results

Ascertaining the modus by which the alimentary tract resists infection after experience with live virus but not following intramuscular vaccination is important from the epidemiological, clinical, and general biological points of view It is hoped that studies of this kind with varying approaches in technique will be conducted by as many workers as can interest themselves in this field

University of Louisville, Kentucky

ALEX J STEIGMAN
MURRAY M LIPTON

STERILISATION OF THE DIABETIC'S SYRINGE

SIR,—The recent correspondence on this subject recommends several methods to be safe and trouble-free

On the one hand, Dr Wauchope (Sept 10) doubted whether sterilisation was necessary and described her fortunate personal experience without any infections for many years But I fear that many insulin patients would have less high standards of cleanliness than hers and this is a very important point not mentioned in the previous correspondence How well I remember a young woman who, after five years of trouble-free injections, developed mysterious abscesses on both thighs The bath she received on admission to hospital for investigation stopped all further troubles, and she told me that she had moved to a house where there was no bath and this explained her abscesses

What do the insulin manufacturers say in their insulin packages? Nothing very definite. Most of them say that boiling in tap-water is desirable but as that is not always possible, advocate keeping the syringe and needles in spirit

The balance of the advice given by your correspondents is to favour spirit alone, although the initiator of the correspondence, Dr Stephen Carter, boils his syringe four times a year and uses no spirit

London, W 1

R D LAWRENCE

SUICIDE

SIR,—Reading Dr Stewart's article of Oct 22 it is difficult not to feel compassion for many of the 85 suicides in his series of 122 who had been suffering from various painful or disabling diseases

Is it not time that the coroner's court formulæ, " while the balance of his mind was disturbed " or " while of unsound mind ", should be discarded in the absence of clear evidence of mental disturbance prior to suicide? Some people who commit suicide to terminate a life that has become a life-sentence of intractable pain are taking a step that seems sensible albeit desperate

As you report last week (p 976), a Bill to provide that suicide and attempted suicide should no longer be criminal offences has been drawn up and approved by the Criminal Law Revision Committee So need we penalise the suicide by casting an unmerited slur on his sanity just because he has committed suicide?

With regard to attempted suicide, Prof E Stengel[1] has for a long time taught that one of its main motivations is the appeal of a desperate individual for help from his fellow-men Unless the family or friends of the attempted suicide are alerted to his dangerous dilemma by the suicidal attempt, the only practical step likely to prevent a second, possibly successful, attempt would seem to be bringing him before the courts and placing him on probation on condition that he receives necessary psychiatric treatment It is to be hoped that this potentially lifesaving course will not be made more difficult if the new Bill becomes law

London, W 1

F R C CASSON

THE NATURE OF ESSENTIAL HYPERTENSION

SIR,—I really must take exception to the data which Dr Marshall (Oct 22) alleges add to the solution of this problem, and the conclusions he draws from these data

My old chief, Sir Thomas Lewis, would not allow readings of blood-pressure taken by nurses to appear in scientific publications The estimations which Dr Marshall uses were made by " specially trained nurses at hourly intervals during one day a patient spent in hospital " They were made to the nearest even number Dr Marshall states that digit preference can be excluded because the nurses had no incentive Nor had those employed by Boe, Humerfelt, and Wedervang[1] in their measurements made on 67,976 inhabitants of Bergen Yet digit preference was more marked than in any other series I know 85% of systolic readings (series I) ended with 0 and only 15% with 5 For diastolic readings the percentages were 87 and 13 respectively Diastolic pressures had a bimodal distribution in the second but not in the first sample This bimodality was most probably due to a change in the team of nurses making the measurements There is no analysis in Dr Marshall's paper of the distribution of readings, nor any evidence that steps were taken to assess how accurate the readings were

As disturbing is his statement " Moreover, the blood-pressure figures used in this study were means of six readings taken under constant conditions " To those who work in the field of science, " constant conditions " has a clear implication, and is a state, in fact, very rarely achieved Dr Marshall's 134 patients " attended hospital for one day during which they rested on a bed in the supine position Their blood-pressure was recorded hourly for six hours by specially trained nurses, who read the sphygmomanometer to the nearest even number " One could perhaps imagine that from 10 to 4 the patients lay on a bed in a side-ward and were visited only by the nurses But this was not so " During the one day in hospital the patients had a physical examination, chemical and microscopic examinations of the urine, estimation of the blood-urea and blood-cholesterol, an electrocardiogram, and a radiographic examination of the heart and skull "

Dr Marshall's averages of six values, each to the nearest even number, will give him a series of integers which perhaps he might take to one place of decimals As set out they are arranged in groups at intervals of 8 or 12 mm Hg He does not say how this grouping has been done And yet it is vital to the conclusion the reader is invited to accept

However, the worst feature of Dr Marshall's paper is his evidence for bimodality A protest has been made before against interpreting irregularities in frequency distribution curves as bimodality, especially when the numbers are small Fortunately Dr Marshall has now brought this practice to what must be the all-time low

---

[1] *Lancet* 1952, i, 1059

[1] Boe J, Humerfelt S, Wedervang, F *Acta med scand* 1957 suppl 321

He says " The systolic pressures of patients over 60 years had a bimodal distribution irrespective of whether their parents died below or above the age of 65 (fig 5) " Fig 5 shows the frequency distribution curve of 26 patients whose parents had died under the age of 65 Here are data taken from fig 5 for this group

Systolic B P	*Frequency %*	*Actual number*
108	4	1
120	12	3
132	4	1
144	8	2
156	12	3
168	24	6
180	16	4
192	8	2
204	12	3
Total	100	25

The contention evidently is that a series 1 3 1 2 3 demonstrates bimodality

Finally, supposing that an analysis of patients between the ages of 31 and 70 showed that there were essentially two populations as regards blood-pressure—and has this not been shown by Dr Marshall ?—could this be accepted as evidence that essential hypertension is the manifestation of a single gene ? For Dr Marshall states " It seems likely that the appearance of a group with raised blood-pressure is caused by a hereditary factor—probably, as Platt suggested, due to a mendelian dominant " It should be clearly stated that cerebral vascular disease consists of at least three entities occlusion of the arteries in the neck, of those within the cranium, and cerebral hæmorrhage There is a strong suspicion that the last is more closely associated with grossly raised pressure than the first of these Dr Marshall says that these patients had " what was judged on clinical grounds to have been a non-embolic cerebral infarction ", but, as previously reported,[2] his trial of anticoagulant treatment had to be stopped because of the incidence of fatal cerebrovascular accidents due to cerebral hæmorrhage in the treated group Had he indeed demonstrated two populations in cases of cerebrovascular disease this would have no bearing whatsoever on whether essential hypertension is or is not the manifestation of a single gene

Oxford G W PICKERING

SIR,—Before some of your readers should be tempted to interpret the results found by Dr Marshall as cogent evidence in the conflict of views on the nature of essential hypertension, could we have the answers to some simple questions ?

(1) We are told that the subjects studied had all previously had what was judged to have been a non-embolic cerebral infarction In what ways were these survivors thought to be representative of all people suffering cerebral infarction, how were the subjects selected, and why were there 91 males and only 43 females when mortality-rates from vascular lesions involving the central nervous system show no gross sex difference

(2) Having demonstrated such very different frequency distributions of arterial pressure in the two sexes as those shown in fig 1 (*b*) and (*c*), what is the justification for combining the two sexes in all subsequent analyses ?

(3) In analysing blood-pressure data for subjects aged 31-70 is it reasonable to use only two age-groups, above and below 60, when the evidence derived from the general population shows arterial pressure to be very sensitive to age ?

(4) The grouping of pressure into units of 12 mm Hg for systolic and 8 mm for diastolic pressure is unusual Could this have influenced the shape of the published curves ?

The type of study carried out by Dr Marshall could
be repeated in many hospitals in the country but
have little value unless confirmed in less highly s
populations Before we are confused by more and
bimodal curves, may I make a plea, Sir, that a
should publish their data in a form that enables int
readers to evaluate them and allows comparison with
published work, and particularly with the careful v
Platt and Pickering Pictures alone are unsatisfac

MODERN CLINICAL BIOCHEMISTRY

R,—I would not put the clock back 50 years as Dr dry forbids (Oct 29), but 113 years and quote from how's paper, Standpoints in Scientific Medicine can learn much from chemistry, but we will have to ve for ourselves the privilege of applying its findings" how was familiar with the appreciable number who e Dr Hendry's outlook in his 1855 paper on Cellular ology he writes "The condescension with which the onents of chemical and physical viewpoints—even e who have only a very imperfect understanding of oscopic anatomy—look down on morphology is known"

om my student days I have had the highest regard for d we receive from competent biochemists if they their right place in the team they are invaluable I ngly dislike splitting the pathology department into or more watertight compartments Whenever I look n my microscope problems in bacteriology, hæmato-y, or biochemistry arise, with the aid of one or other mber of my team these are followed to the advantage of clinician and patient Our biochemist regularly draws attention to problems which should be followed in er departments Without a medical training very few chemists are safe in advising on the meaning of many their findings A good example of the interdependence the four departments of the pathological laboratory was man of 23 admitted to one of our surgical wards in a ate of diabetic coma When the biochemist told me of s very high blood-sugar I at once asked why he was in a urgical ward it was because he had had a bladder-neck peration for enuresis there three months before I dis-overed that he was not then a diabetic, so we at once amined his blood for severity of infection (if any), and is urine for pus and organisms The real diagnosis was uickly established as pyonephrosis, and unfortunately roved at necropsy To me all sections of the laboratory e equally important in general Who is the most impor-nt departmental head varies with the case, for the young an just mentioned I would say it was the hæmatologist ecause he said clearly death from infection is inevitable the absence of successful treatment

The question of who is the most important, the patho-gist or one or other of the technical heads of departments, an absurd one It is well answered by Leo Tolstoy in s short story Three Questions written in 1903 (in *wenty-Three Tales*) I hope Dr Hendry and others who ink like him will read this The practical point is that pathologist is usually the only one who can bring all ctions of the laboratory to the aid of the clinician, he ove all others can cheat death when he calls too soon he greatest emotional satisfaction is to be found in neral practice, the greatest intellectual satisfaction in the ological department The former is warm, the latter o often cold, that is why many of us feel like Dr Hendry t times If this emotional satisfaction is wanted, do not ecome a physician or surgeon as Professor Cappell ossibly suggests, for they occupy a half-way position, btain a medical qualification and enter general practice

Dr Hendry may be shocked to know that to me the biochemist ranks equally with the senior technician in harge of hæmatology, bacteriology, and histology I do not know which is the most important until I know the blem If the training of a biochemist is more difficult, d all will not agree with this, they should be paid re—as they are This makes a psychological barrier een them and the technical heads of the other departments which a wise biochemist will do all in his power to destroy

Biochemists are not at the crossroads looking four ways at once at the moment they are looking on the way out only If that happens it will be a tragedy We do not have far to look to see non-medical biochemists who are invaluable in the practice of medicine, they are professors or of that calibre This is taken to mean, by some, that all we need to do to obtain a good biochemical service is to appoint a good chemist in charge of it and then keep away This is nonsense My biochemistry department owes a lot to men with medical qualifications, these are ideal but in short supply Even Dr Hendry might allow that the greatest clinical biochemist of all time was the medically qualified Paul Ehrlich

How should the pathological services of the future be planned? Division into a number of watertight compartments is an evil which may be necessary in places The right thing seems to me a large general clinical laboratory where a problem in a patient is studied, not just a test performed This should be backed by small reference laboratories in the same building Most of the routine biochemistry should be done in the clinical laboratory—including the blood sugars and ureas for which Dr Hendry has such contempt, though if I could have only two biochemical investigations I would pick these

How should junior and senior members of the medical profession use the pathological services? I give two answers to this Because so many tests are needed the pathologist can no longer attend to all Many are straightforward and the patient progresses well, these cases justify a request for a given test Many patients are diagnostic problems or are unsatisfactory If a patient is, say, unsatisfactory after an abdominal operation I like the surgeon to tell me what he did and invite our help At the moment many are obsessed with biochemistry to the exclusion of the other branches The correct use of all departments will invariably say peritonitis, ileus, both or neither We want to know the process, not some minute detail of it When we begin our training with the microscope we use the highest magnification we can get, and feel that if we could only obtain something larger we would know everything As we become more experienced we use the lowest magnification so that we can see the process This earns us scorn from the most junior my son, when a dental student, assured me that I only guessed at such a low magnification I fancy that many, who should know better, feel that in biochemistry they have something of higher magnification than the electron microscope Perhaps they have, but the sap in a leaf tells you little about the plant and less about the forest.

May biochemists read Leo Tolstoy and remain our honoured colleagues May I be permitted to salute Professor Cappell's masterly survey

Derbyshire Royal Infirmary,
Derby

G R OSBORN

SIR,—There is an element of truth in Dr Hendry's statements about the interrelationship of "pathologist" and biochemists, but surely many will think he overstates his case, and confuses any serious analysis of the position, both by his caustic wit and blatant misuse of the names of the reactants It is patently absurd to imply that each large hospital should have an autonomous biochemistry department such a separist movement would be harmful to the patient and the clinician, and more particularly to

the biochemist himself What is clearly needed is a greater integration of the laboratory services, both within their own house and within the framework of the hospital as a whole No hospital worker, be he physician, surgeon, histologist, or biochemist, can go it alone, even if the latter thinks he can do it all himself It is, of course, platitudinous to say there is no place for the enthusiastic amateur in this modern scientific work, each specialist must overtly be trained as such, but he would be a fool indeed to suppose he alone has something to offer the patient, whatever the latter's disease

Pathology is the study of disease however Dr Hendry may interpret biochemistry to himself, in clinical practice it is the application of chemistry to the study of human disease, and it must follow that even he is to some extent a pathologist I personally would like the terms pathologist and pathology laboratory, as currently used, to be discontinued, in hospitals at least Instead, the terms bacteriologist, biochemist, biophysicist, hæmatologist, histologist, or virologist could be used according to taste each worker should have an individual laboratory, but all should be contiguous and in one central building, so having common meeting and stamping grounds Medicine and pathology have both suffered enough enthusiastic divisionists already without further chemical schizists

HYDROCORTISONE AND CORTICOTROPHIN IN HERPES ZOSTER

Sir,—During the past three months I have been using short courses of intensive hydrocortisone 10 mg t i d for four days in severe cases of herpes zoster—with dramatic results

Severe pain is relieved in two days and herpetic vesicles seem to scab and separate at an earlier period This has been particularly noticeable in severe herpes of the ophthalmic division of the 5th nerve This treatment has also been used for herpes involving cutaneous branches of the brachial plexus, again with dramatic improvement

I do not seem to have seen this reported elsewhere The same improvement has been seen with the use of corticotrophin long-acting gel (40 units six-hourly for three days)

VIRUS INFECTIONS DURING PREGNANCY

Sir,—I read your leader of Oct 8 with much interest, because it fell to me to review this topic at the First International Conference on Congenital Malformations held in London in July, 1960

May I take this opportunity to encourage those readers who may be continuing to investigate the outcome of rubella in pregnancy to arrange for the assistance of a laboratory where virus diagnostic tests can be performed?

Although the rubella virus has not yet been isolated—and we have had many negative results in Toronto—the Echo viruses that may cause a similar clinical syndrome can be readily grown in tissue culture

Work done on the Echo viruses in Canada and many other parts of the world has convinced me that a diagnosis of "rubella" or "german measles" obtained from a patient must be considered unreliable Even a physician may mistake infection with an Echo virus (especially type 9) for rubella In differentiation, it is important to note the short incubation period of Echo infections (3–5 days)

Epidemiological studies such as those commented on in your editorial have produced substantial results Such studies may, however, prove even more rewarding in th future when epidemiological techniques are correl with the more precise laboratory techniques of th modern medical virologist

HAZARDS OF BARIUM-SULPHATE ENEMA

Sir,—Your annotation of Oct 8 refers to barium sulphate pulmonary embolism The following case may therefore be of interest as a record of a further hazard in relation to this common diagnostic procedure

A fit man of 70 was referred from the outpatient department for barium enema He complained of mucous diarrhœa Technically the enema was uneventful On walking from the X-ray table he complained of sudden severe abdominal pain and collapsed to the floor The radiologist reported that he was unconscious for some seconds He was transferred immediately to a general medical ward

When examined he was conscious, complaining of generalised abdominal pain and mentioned a transient sharp left-sided chest pain No peripheral pulses were detectable, blood pressure was unrecordable and the jugular venous pressure was raised It was then observed that a striking generalised erythema was developing it reached a maximum some 45 minutes after completion of the enema, and faded gradually over the next 6 hours

Immediate resuscitation was symptomatic, using oxygen, *morphine, intravenous pressor agents, and intramuscular* promethazine Chest X-ray, plain X-ray of the abdomen, electrocardiogram, serum-transaminases, and urinary 5-hydroxyindole-acetic acid were all subsequently shown to be normal The barium enema showed a few diverticula in the sigmoid colon but no other abnormality The patient made an uneventful recovery and was discharged 10 days later The cause of his abdominal pain remains obscure

In view of the negative findings and the clinical picture, this man may have had an acute hypersensitivity reaction The barium enema was made up in 1% tannic acid and was preceded by colonic irrigation with tap-water followed by 'Veripaque' enema A similar investigation 4 months previously with the same preparation was entirely uneventful Skin tests using 1% tannic acid were negative

Fatal collapse due to proven barium-sulphate pulmonary embolism has now been reported [1] A second case in which this diagnosis seems highly probable, although necropsy was not allowed, has recently been recorded [2] Acute "water intoxication" in the preparation of children for barium enema is now a well-recognised and sometimes fatal hazard [3–5] But the condition I have described does not seem to have been recorded previously

Over 1000 barium enemas are performed annually in this hospital, no member of the staff of the department of radiology has seen or heard of a similar case Although,

GEORGE X TRIMBLE

ORAL TREATMENT OF PERNICIOUS ANÆMIA WITH LOW DOSES OF H P P /1

SIR,—Dr Varadi (Oct 15) must realise how increasingly ifficult it has now become for us to assess the significance f his findings, faced as we are with three differing escriptions of the treatment given, and the responses btained, from the same ten cases It is also a matter of ome surprise to find that he classifies a case as " relapsed " Sept 17) when, in fact, the patient did not suffer a eterioration in the blood-picture at all, but merely a fall n the serum-B_{12} level when the daily dose was reduced rom 300 μg to 100 μg of B_{12}

Finally, it is a little disappointing that Dr Varadi has till declined to explain the scientific basis of his interretation of serum-B_{12} levels, when applied to this articular form of therapy We do not doubt that the stimation may be of some value in confirming a diagnosis n the untreated case of pernicious anæmia, but we would ike to know what evidence he has for the conclusion in the enultimate paragraph of his letter of Sept 17, that erum-B_{12} levels also reflect the degree of intestinal bsorption, *on this particular form of therapy*

F S MOONEY
J G HEATHCOTE

St Helens Hospital

SIR,—Like Dr Varadi and Mr Elwis (Sept 17) I have been investigating the serum-vitamin-B_{12} levels of patients with pernicious anæmia in relapse who have been treated with vitamin-B_{12}/peptide (' Distivit ')

In 8 such patients receiving 200 μg daily or less, followed for periods of three to eighteen months, the serum-B_{12} concentration rose above 200 μμg per ml in 1 case only A further 2 patients given 500 μg daily for a period of eighteen months maintained serum levels around 400 μμg per ml These results are broadly similar to those previously reported [4] using oral crystalline vitamin B_1 With the exception of 1 patient receiving 100 μg daily, all these cases reached and maintained normal values of hæmoglobin, red-cell counts, and packed-cell volumes, so Dr Mooney and Dr Heathcote (Oct 1) could again, on this evidence alone, question the scientific basis for using serum-vitamin-B_{12} levels as proof of adequate dosage I submit however that, as a general concept of rational therapy, it is desirable to give a sufficient amount of the vitamin to maintain the serum level near the average normal mean—that is, about 400 μμg per ml It therefore seems necessary, if oral treatment for pernicious anæmia is considered desirable for a particular patient, that over 200 μg daily should be administered, whether the vitamin B_{12} is in a crystalline form or a peptide complex

BROADER MEDICAL TEACHING

SIR,—May I comment on vour interesting annotation Broader Medical Teaching (Oct 22) ?

On Oct 23, 500 general practitioners attended our third *Medical World* Conference One of the subjects was " Training for General Practice " From the discussion, several attitudes became apparent

(*a*) The G P s agreed unanimously that their medical-school training had not fitted them for their work, (*b*) that, with few exceptions, hospital doctors who had trained them had little knowledge or understanding of the problems facing the G P , (*c*) that, despite a growing awareness of these deficiencies in training, the situation has not improved of recent years

In a laudable attempt to correct an unbalanced system of training, some universities and the College of General Practitioners have introduced schemes to allow medical students to see something of general practice during their training Apart from local schemes which allow students to spend a few weeks with selected G P s, there are the Edinburgh and Manchester University schemes On a more ambitious scale the Inverness Regional Hospital Board is providing rotating internships, which include attachment to G P s, and the Wessex scheme financed by one of the Nuffield Trusts is seeking to provide young G P s with a chance to see something of all three branches of the Service

No-one would wish to minimise these efforts Yet surely they leave the main problem unsolved The hospital teacher who will continue to form the minds of new generations of students is still out of touch with the problem of general practice How can this be otherwise when the career structure in the hospital field demands that the young trainee consultant should unremittingly follow the narrow lines of his specialty ?

I suggested at our conference that the problem could be partly solved if every future teacher in the hospital service had to spend a period in general practice—a proposal which was warmly welcomed The time to do so would be between the registrar and senior-registrar appointments—i e , before the young specialist sets his foot on the ladder from which he dare not fall off If the time spent in general practice were made a condition of appointment to a senior-registrar post, no-one would gain an unfair advantage

Unlike the G P trainees, these young aspiring specialists would not have to be taught general practice by selected good G P s Their need is to see the realities of practice in all its forms They could be attached to four different types of practice for six weeks each, and could learn quickly some of the problems facing the industrial, semi-urban, rural, and seaside G P In all, this would occupy only six months of their working lives, yet it could have a profound and beneficial effect on the future training of the medical student—and, indeed, on British medicine

Obituary

ALAN BROWN

M D Toronto, F R C P (C), F R C P

Dr Alan Brown was one of the pioneers of pædiatrics in Canada For over thirty years he was physician-in-chief to the Hospital for Sick Children in Toronto, and when a chair of pædiatrics was set up in the University of Toronto in 1935 he was appointed the first professor He died on Sept 7 at the age of 73

He qualified from the University of Toronto in 1909, and spent five years as a resident physician in the Babies' Hospital (Columbia University), New York After further postgraduate study in Germany, Austria, Denmark, and Britain, he was appointed to the medical staff of the Hospital for Sick Children in Toronto in 1915 Four years later he became its physician-in-chief Under his direction the hospital became a centre for the training of medical undergraduates, pædiatricians, and nurses In 1919 he was appointed an associate professor of medicine in the university, and in 1935 head of the newly created department of pædiatrics He served for many years as consultant to the local, provincial, and national departments of health, as well as to three other Toronto hospitals and the former Infants' Home He was a founder and past president of the Canadian Pædiatric Society He retired from his hospital appointments and his chair in 1951

As a writer and a visitor he was well known on both sides of the Atlantic His book on *The Normal Child*, first published in 1926, is now in its fifth edition, and with Dr F F Tisdall he published a useful survey of *Common Procedures in the Practice of Pædiatrics* He gave many clinical lectures, and his colleagues in this country will recall his Ingleby lectures in 1948 on the scientific construction of the normal child's diet He was a corresponding member of the British Pædiatric Society and was elected F R C P in 1940

E C R writes

"Alan Brown crusaded vigorously for many improvements in the care of infants and children, including the proper formulation and sterilisation of infant feedings, the compulsory pasteurisation of milk, and the universal use of diphtheria toxoid and other well-established immunisation procedures Soon after he became physician-in-chief, he organised a small research laboratory at the hospital which, with his support and encouragement, has grown greatly with the years in both size and reputation Canadian pædiatrics in general and the Hospital for Sick Children in particular owe a great deal to his vision, unusual energy, and outstanding organising ability "

Dr Brown married Miss Constance Hobbs in 1914 She survives him with their two daughters

CLAUDE WILFRED ALFRED KIMBELL

M B N Z , F R C O G , F R C S E

Mr Claude Kimbell, gynæcological surgeon to the Samaritan Hospital for Women, London, died on Oct 26 at the age of 55

A New Zealander by birth, he was educated at Wellington College and the University of Otago, where he graduated M B in 1930 The following year he came to this country for postgraduate studies, and in 1935 he took the F R C S E and in 1937 the M R C O G During the late war he served in the R.A M C with the rank of major He remained behind at Dunkirk to look after the wounded and spent the rest of the war as a prisoner in Germany Afterwards he returned to practise obstetrics and gynæcology in London and was appointed to the staff of the Samaritan Hospital and the City of London Maternity Hospital He was elected F R C O G in 1953 He was a founder member of the Gynæcological Travellers' Club

C M G , one of his colleagues at the Samaritan Hospital, writes

"Claude Kimbell was a sick man for many years, but because of his courage and interest in life he continued with his work In the Samaritan Hospital he was loved by everyone he worked with in the outpatient department, wards, and theatre. An excellent surgeon, he was interested in the total human and always concerned with the psychological implications of a case He was a perfectionist and ever ready to sacrifice himself for his patients and friends From his experience as a prisoner-of war he had learned not bitterness but a deep sympathy and understanding of his fellows "

J H , who first met Kimbell twenty-five years ago on visits to Liverpool when Kimbell stayed with his fellow New Zealander, the late Charles Marshall, came to admire "his many qualities as friend and surgeon" He relates

"Knowing that his health was failing Kimbell lately made a trip to Canada as a ship's surgeon to see his married daughter and grandchildren In a Newfoundland hospital he found a sailor who had been seriously injured four months previously No one would take the responsibility to send the sailor back to England and his family It was typical of Claude Kimbell that he organised a passage home on his own ship for this injured man, and on arrival in Liverpool with great energy arranged for him to be sent home to his family

"As a surgeon Kimbell was meticulous in detail and deft in technique As a man I can sum him up in four words—modest, honest, generous, and always considerate of others "

Public Health

The Registrar General's Commentary

IN his commentary on the vital statistics for 1958 the Registrar General[1] notes that the birth-rate of 16 4 per 1000 was the highest recorded since 1949 There were 740,715 live births, the largest number since 1948 The birth-rate per 1000 women aged 15–44 was 82 1 in 1958, which was above the level of the early 1920s and 32% higher than the 1938 rate The birth-rate was highest in Merseyside and lowest in Greater London

Population —The annual rate of increase amounted to about 0 5% of the population, a little less than the average rate of population increase for Northern and Western Europe, and only a third of the rate of increase in Asia The estimated total population at mid-1958 was 45,244,000 (21,877,000 were males and 23,367,000 females)

Marriages —In the 15–24 age-group, the proportion married has more than doubled since 1931 for both men and women Although total marriages were 7000 less than in 1957, the rates continued to rise slightly at the younger ages In 1954, 6 9% of bridegrooms and 28 6% of brides were minors, the corresponding figures for 1958 were 10 7% of bridegrooms and 35% of brides

Deaths —The crude death-rate—11 7 per 1000 persons of all ages—showed little change With allowance for population age-changes, the average reduction in mortality has been 60% in the past fifty years, and 40% in the past twenty-five years Between 15 and 24 years, the death-rate for males is more than double that for females, in this age-group seven times as many men as women die from accidents

Infant mortality —This continued to decrease deaths of children under 1 year numbered 22 5 per 1000 births in 1958, the lowest rate recorded till then Infant mortality as a whole has declined by two-thirds since 1928

Tuberculosis —There were 4480 deaths in 1958, compared with 19,797 in 1949 In the same time, annual notifications have declined from over 50,000 to 30,000

---

[1] Registrar General's Statistical Review of England and Wales, 1958 Part III, Commentary H.M Stationery Office Pp 222 13s

Accidental and violent deaths.—These have increased progressively, the totals being 18,513 in 1949 and 22,456 in 1958. The increase is due mostly to increases in motor-vehicle accidents, accidental gas-poisoning, falls, and, in women only, suicide. The death-rate among men in the 15-24 age-group from motor-vehicle accidents increased from 26 per 100,000 population in 1954 to 35 in 1958. Accidental deaths attributed to barbiturate poisoning increased from 77 in 1949 to 205 in 1958, and to domestic gas from 421 to 870.

The September Quarter

In England and Wales in the September quarter, 1960, there were 197,572 live births, 3873 stillbirths, and 112,379 deaths.[1] The birth-rate (17.2 per 1000 population) was the highest for a September quarter since 1948, when the corresponding rate was 17.5. The stillbirth-rate was low—19.2 per 1000 live and still births.

Parliament

Professions Supplementary to Medicine Bill

THIS Bill received the Royal Assent on Oct. 27. Its provisions will not come into operation until they are brought into force by Orders in Council.

QUESTION TIME

Hospital Casualty Services

Earl WINTERTON asked the Government whether, in view of the criticisms made by an unofficial committee of the methods for dealing with casualty cases in National Health Service hospitals and of other evidence to the same effect, they would appoint a committee of inquiry.—Lord ST. OSWALD replied: My Lords, the Standing Medical Advisory Committee of the Central Health Services Council appointed, earlier this year, a subcommittee, under the chairmanship of Sir Harry Platt, to consider the organisation of hospital casualty and accident services and to make recommendations regarding their future development. The Scottish Health Services Council has set up a similar committee. I have no doubt that these committees will consider the recommendations made in the study, based on 20 casualty departments, which was recently published for the Nuffield Provincial Hospitals Trust.

Lord STONHAM: Is the noble Lord aware that, at the instance of the Minister, every regional board has been considering this problem, that they are proposing to concentrate major casualty centres in the hospitals in each group, but that what is needed is more money to equip, expand, and provide more casualty centres? And can he say whether that will be forthcoming?—Lord ST. OSWALD: I think that any decisions of that nature must naturally rest upon the finding of this subcommittee, which has been set up specifically for the purpose of discovering what the facts are, and of suggesting remedies.

Means Test for State Scholarships

Mrs EIRENE WHITE asked the Minister of Education what decision had been reached on the recommendations of the Anderson Committee on parental means tests for university students.—Sir DAVID ECCLES replied: I shall very shortly announce a radical revision of the present means test, to be brought in by the autumn of 1961. This is without prejudice to the abolition of the means test if that, on full examination, should turn out to be required.

Smokeless Zones

On Oct. 1 there were 296 smokeless zones or smoke-control orders in operation in England and Wales, covering 255,974 premises, and 98 more smoke-control orders, covering 123,219 premises, have been confirmed but were not in operation. Some 1270 local authorities have not made smoke control orders, but most of these do not have a major problem of domestic smoke pollution.

Notes and News

WORLD HEALTH ORGANISATION

THE Director-General of W.H.O., Dr M. G. Candau, and the retiring senior W.H.O. representative in the Congo, Dr J. S. MacKenzie Pollock, have both reported on the medical situation there.

In July W.H.O. responded to a request by the Security Council, and within a week 28 staff members had been sent to the Congo. 28 medical teams provided by 25 national Red Cross societies answered a joint appeal by the League of Red Cross Societies and the International Committee of the Red Cross. These teams were initially to stay three months. Some countries offered additional assistance, and soon hospitals, not only in the cities, but in the country as well, were able to function again.

At each provincial capital, except that of Katanga, there is a W.H.O. group, consisting of a public-health adviser, a public-health engineer, and a mobile epidemiological team. These mobile teams have already begun to organise vaccination campaigns against smallpox, typhoid fever, yellow fever, and plague. To deal with these diseases and the other major health hazards—malaria, filariasis, leprosy, and tuberculosis—many staff members are being recruited. They will be paid out of the U.N. Congo fund and placed at the disposal of the Congo Government. The main need is to staff the district services with doctors who will superintend the hospitals and organise preventive health services. 130 health personnel are being recruited now, and this number will soon be increased to about 500. The Red Cross teams have been asked to remain for six months, or longer if possible.

The long-term problems can be solved only by training Congolese doctors. There are none at present, and the local university, Lovanium, will graduate only 2 in 1961, and not more than 19 in all by 1965. Dr Candau considers that the 1959 situation cannot be regained in less than twelve to fifteen years. But an encouraging start has been made. W.H.O. is providing 13 additional teaching staff, including the first professor of public health, which has enabled Lovanium University to increase its medical-student intake to 40. The three schools for "medical assistants" will finish the six-year training of the present students and then close. All students after that will complete the full medical course at Lovanium University. 74 "medical assistants" are at present helping to provide essential health services.

Meanwhile 60 "medical assistants" have been awarded W.H.O. fellowships and have left for French medical schools to qualify as doctors after special two-year or three-year courses. 7 students with no previous training have been awarded fellowships for a full medical course in France or Switzerland.

Dr A. Bellerive (Haiti) succeeds Dr McKenzie Pollock as senior W.H.O. representative.

In Geneva, the 26th session of the Executive Board opened on Oct. 25. Dr Henrique M. Penido (Brazil) was elected chairman.

THE WORLD'S FOOD

"Food and population are two of the crucial determinants of the future of mankind. Freedom from hunger in the less developed countries of the world, however, is not simply a matter of regaining or maintaining pre-war levels of per caput production and consumption. ... Much greater increases in food production in these regions are needed before any real progress can be made in stamping out hunger and malnutrition. But increased food production must go hand in hand with general economic development so that consumers can afford the additional food and the better quality food they need."

In these words, taken from his foreword to F.A.O.'s latest annual report,[1] the Director-General summarises the agricultural problem confronting the greater part of the human race. While the highly developed countries continue to increase production (to the point of accumulating surpluses) by

A Medical Staff Residence

On Oct 18, at Odstock Hospital, Salisbury, a new residence for medical staff was officially opened by Mr P G Templeman, chairman of the Wessex Regional Hospital Board

The residence has 17 bed sitting rooms each with its own wash-hand basin and built in furniture A large lounge is separated from the dining room by sliding doors and meals are served from a small service kitchen adjoining the dining room There is a library away from the living-room area Two flats for married residents have been built beside the new residence The flats are furnished and centrally heated, and each has a lounge/dining room, kitchen, main bedroom, and spare room The cost of the whole scheme, including furnishings, was £35,000

Award for Medical Film

La Presse Médicale is again offering a prize (1000 NF) for a medical 16 mm film whose time of projection does not exceed 30 minutes Films should be sent to the journal, 120, boulevard Saint-Germain, Paris VI^e^, before Feb 1

Caloric Balance in Man

The Nutrition Society is to hold a symposium on this subject on Saturday, Dec 17, at the Middlesex Hospital Medical School, London, W 1 The speakers will be Dr J V G A Durnin, Dr O G Edholm, Dr Raymond Greene, Dr I M Chalmers, Dr G C Kennedy, Dr A M Thomson, Dr F E Hytten, and Dr E M Widdowson Further particulars may be had from the hon programmes secretary of the society, Miss D F Hollingsworth, c/o Ministry of Agriculture, Fisheries and Food, Great Westminster House, Horseferry Road, S W 1

A meeting of the Biochemical Society is to be held on Friday, Nov 18, at 10 A M, at the Middlesex Hospital Medical School, London, W 1, when there will be a colloquium on histochemistry

Professor J B Duguid, who has lately retired from the chair of pathology in the University of Durham, has left for Malaya, where he is to be an adviser in histopathology under the Technical Cooperation Scheme of the Colombo Plan

The Association of Universities of the British Commonwealth (36, Gordon Square, London, W C 1) have published a list of fellowships, scholarships, and grants tenable at universities in the United Kingdom and a short list of awards tenable outside the United Kingdom Copies are being sent to universities and libraries and to other institutions on request

A committee meeting of the Group for Representation of the Views of Clinical Psychiatrists will be held on Thursday, Nov 10, at 5 30 P M, at Tavistock House North, Tavistock Square, London, W C 1

The London Medical Exhibition will be held in the New Hall of the Royal Horticultural Society, Westminster, from Nov 11 to 18

University College London will hold a reunion dinner at the college on Friday, Feb 17, for undergraduates or postgraduates who entered before 1918 Early applications for invitations should be made to the assistant secretary of the college, Gower Street, W C 1

From Nov 21 the address of the National Council for the Unmarried Mother and Her Child will be 255, Kentish Town Road, London, N W 5

Film about Handicapped Children—The Cine Club of Bristol, with the help of the South Western Regional Hospital Board and the Bristol education and health committees, has produced *Claremont*, which shows how children with spastic disabilities are educated and treated at a school at Claremont, Bristol The film, which is in 16 mm colour, has a sound commentary and lasts about 12 minutes The hiring fee is 1 guinea Applications should be sent to the medical officer of health, central health clinic, Tower Hill, Bristol, 2

CORRIGENDUM *Treatment of Urticaria*—The dose of proguanil ('Paludrine') mentioned in Sir Charles Dodds' letter of Oct 22 should have been 0 1 g (100 mg)

PREPARATION FOR THE PROFESSION *

The Present and the Future

JOHN ELLIS
M B E , M A , M D Cantab , F R C P
PHYSICIAN TO THE LONDON HOSPITAL, LONDON, E 1, AND TO THE PRINCE OF WALES GENERAL HOSPITAL, SECRETARY TO THE ASSOCIATION FOR THE STUDY OF MEDICAL EDUCATION

THERE are periods in the history of every country when the form of medical education is appropriate to the pattern of medical practice, and when that pattern is itself suitable to the medicine of the day, so that all knowledge can be applied effectively and ethically The standard of medicine is then as high as the degree of knowledge will allow, for medicine is in balance

Such a period comes to an end when there is a major advance in medical knowledge This advance passes very rapidly into practice and changes the pattern of it The change of practice then alters medical education, and if all goes well balance is restored

It is our particular good fortune to belong to medicine when it is again changing, or to be accurate has just changed The increase of knowledge has enforced specialisation—which itself ensures that knowledge will continue to grow at speed But, because in Britain no-one now lives far from a specialist, the general practitioner is prevented from doing much of the therapeutic job he was trained for Instead, he is left with an overwhelming amount of other problems of diagnosis, treatment, and prevention of disease, for which he was not trained He must transfer many patients to the care of another doctor, and he must be sure that he chooses the right specialty

While this increase in knowledge has thus been altering the pattern of practice, a change in the quality of knowledge has altered the doctor's concept of disease His attitude to diagnosis and treatment has become more scientific

But it must be noted that the change is in attitude to disease and not in attitude to the patient The problem of medical education is how to inculcate the scientific attitude while maintaining the highest standard of clinical skill and the most humanitarian concern for the patient as a person

* * *

It took us quite a long time to accept that with the coming of specialisation had come the end of general practice as we knew it, and also the end of the apprenticeship training which it had evolved for itself During that time an inevitable disruption of medical education has been intensified, more in some schools than others, by our continuing to produce general practitioners of a kind no longer required, by a system of apprenticeship to specialists which could not be successful anyway

However, that era of uncertainty as to the aims and objects of medical education is over It ended, in fact, several years ago when the General Medical Council in its *Recommendations* of May, 1957, officially stated that the aim is no longer to produce, by the time of qualification, a finished doctor of any kind In future medical education, for family doctors as well as for specialists, is to consist of two portions, undergraduate and postgraduate The significance of this radical change has not yet been fully appreciated for several reasons One is that a year of internship after qualification had become compulsory before 1957, and therefore the G M C 's action appeared to some to be no more than giving official blessing to something which had already happened A second is that, because medical education in this country is very rarely the primary concern of anyone, very many of those actively engaged in it have not yet read the G M C 's recommendations A third is that, in contrast to all its previous announcements the G M C did not specify in detail the nature of either a minimum undergraduate education or a minimum postgraduate training It very wisely left the onus of creating a new pattern of undergraduate education to each individual university and medical school, stating that this pattern must provide a sound basis for further study, by ensuring that the student not only acquires knowledge and clinical skill but also scientific method, he is to be given an education as well as a training This freedom is obviously essential if each of our 26 schools is to be able to develop new enterprise to the best of its capabilities, but initially of course it can act as a stimulus to progress only in those schools where the desire for progress exists

Thus, though medical education in this country has passed out of the phase of catabolism into the phase of anabolism, the signs of this are not to be seen in every university Some schools have set a new course for a new educational objective and are under way, some are drifting out of control, some are in the doldrums, and some are being blown far off course—even off their original course—by the contrary winds of contemporary medical practice It is inevitable that some will have a greater proportion of teachers who are firmly attached to the old form of training, but it is equally inevitable that these teachers, by their resistance to change, will demolish the pattern they seek to preserve It is natural that those schools which have been most successful in the application of one method should be the last to realise that it does not work any more The man who has for years travelled to his destination in a Rolls-Royce does not think of getting rid of it—until he discovers that others are getting there more satisfactorily in an aeroplane—with Rolls-Royce engines, of course

There is therefore cause for neither surprise nor lament in our present state of medical education, save in one respect Speed of adaption is obviously important and it does appear that this could be unnecessarily slowed in London About half of our medical students receive at least their clinical training in the 12 London medical schools Inequitable as it may seem, a faculty which has 12 separate schools is unable to move 12 times as fast as other universities, and is more likely to resemble a convoy whose speed is always that of the slowest ship It is always difficult for the commodore of a convoy to give the order " All ships to proceed at their best speed " It is true that in this case precisely that order has been given to the whole medical-education navy by the G M C , but there is in this country a well-known precedent for turning a blind eye to the receipt of a naval signal

* * *

---

* Extracts from the Wood-Jones lecture delivered in the University of Manchester Medical School on Feb 9, 1960 An abridged version of the lecture appears in the October issue of the *Manchester Medical Gazette*

However, all schools have been charged with the duty of adapting their education to meet modern conditions and needs, and most have already begun to do this.

At first sight they appear to be up against an insuperable difficulty—that of deciding how much knowledge and how much training is to be in the undergraduate years, and how much in the postgraduate. These questions seem difficult to answer in view of the fact that the responsibility for the postgraduate years is shared by the university with many other organisations, including the Royal Colleges and the Ministry of Health, and no one of them has sole authority. Furthermore, nobody could at the moment be precise as to how much knowledge and how much technical skill is necessary for the minimum effective practice of any branch of medicine, particularly as the function of the family doctor is not yet clearly defined.

But the fact that we do not know these things need not inhibit the reform of undergraduate education at all. For the aim of this, now, is first and foremost to *educate*—i.e., to give the student *not* knowledge but the power to utilise knowledge.

That he must know facts is obvious, and that in his early days he cannot find these out for himself but must be given them is equally obvious. His and his teachers' primary purpose, however, must be that he learns how to learn for himself. Therefore the factual content of the undergraduate period does not have to be any particular percentage of the total of medical knowledge; it has to be chosen for its relevance to future learning, not for its relevance to future practice. Equally important, the student's progress must be assessed *primarily* on his ability to reason and utilise knowledge, and not merely in terms of the amount he knows. Similarly his clinical proficiency must be judged on the soundness of his method, of which the correctness of the physical signs he elicits from a patient in an examination is but one indication. By the same token, if it be true, as is sometimes claimed, that the newly qualified of today know more than their predecessors ever did, this does not mean that all is really well with medical education.

If the object of undergraduate education is achieved, then gaps in knowledge and inadequacy of technique will be made good in the postgraduate period. If the object of undergraduate education is not achieved, then such gaps will probably remain for ever, and he will be largely denied the mastery of new data and the critical evaluation of new treatment. Though specialisation has come to stay, there is nothing the least static about the size or form of any particular specialty. The future happiness and success of specialist and general practitioner alike depend on his ability to learn and on his knowledge of general principles.

The following should be our objectives:

1. The student must learn how to learn for himself.
2. He must acquire a scientific method of thought—i.e., the power to reason and think critically.
3. He must achieve competence in clinical method—i.e., the techniques of obtaining information from patients.
4. He must gain an understanding of the responsibilities of a professional person.

If these objectives are reached the student will inevitably have built up a foundation of knowledge, including empirical knowledge. He will also have built a foundation of clinical experience, as regards the diagnosis, treatment, and prevention of disease on the one hand and the nature of man on the other. The exact content of the foundations of knowledge and experience will vary, but during the years of his postgraduate training, each student will be able to fill in those gaps relevant to his own future practice.

* * *

The undergraduate course of studies, thus freed from the need to include all or even any fixed percentage of knowledge and technique, can now, and must now, be based on considerations of the processes of learning.

This granted, it is at once evident that many different arrangements of studies have much to commend them in theory. Until they have been tried in practice, there can be no way of judging between them, and in any case the judgment can be no more than a clinical one. It is therefore idle to speak of the curriculum as though there is somewhere a correct arrangement which will be correct for every school and every student. The best curriculum for any particular school is that which enables it to make the best educational use of all its facilities and enables its students to progress through successive stages of learning, each with a clearly defined objective.

The number and sequence of stages, together with the purpose and content of each, will vary from school to school, but there are certain requirements which must be met in every stage everywhere:

1. Its purpose must be equally clear to both teachers and taught.
2. There must be deployed in it those incentives to study which are relevant to that purpose.
3. There must be built into it such forms of assessment of the student's progress as are appropriate to its content.

It goes without saying that other objectives, contrary incentives, and inappropriate tests should be excluded as rigidly as possible.

A course of studies of this kind cannot be made by a mere alteration of the timetable, even if this is done with educational objectives in mind. An entirely new attitude to teaching is required, and reform of the curriculum will be ineffectual unless there is also a reform of the method by which the curriculum is devised, applied, and constantly assessed. In my opinion this is no longer a matter of administration from the dean's office. There is required for each stage of the course a team of men who are responsible for it. They should represent all those departments most closely concerned with that stage, together with others whose advice could be helpful, even if they are not likely to teach in it themselves. For example, preclinical teachers should be concerned with the planning and assessment of predominantly clinical stages, and clinicians with the predominantly preclinical stages.

The team should, moreover, be representative of whole-time and part-time teachers, thus ensuring that the largest possible number of all kinds of teacher are closely involved in the educational effort. In this way cooperation can be achieved, for, instead of every department competing for what it feels is its rightful portion of the student's time, each becomes more concerned with what it has to contribute to the common purpose of each stage of the student's development. Furthermore, it is only when a teacher is able to appreciate the overall picture of that development that he can judge at what stage his own subject can make its best contribution. At present the resources of a special department are often squandered because students are routed through it too early or too late. Frequently also a student is able to attend a department for one period only, although it has something to offer him at several stages.

The effective planning, execution, and frequent assessment of every stage of a real course of studies is quite beyond the capabilities of anv dean's staff or curriculum committee, but every school could muster a team for each stage Each team would be working towards a comprehensible and realisable objective, and would be able to define the content of knowledge and practical experience, deploy relevant incentives, and devise appropriate forms of assessment If integration of staff were ensured, the student would be helped to integrate his knowledge for himself without the aid of elaborate timetable innovations —and neither the autonomy of departments nor the freedom of individual teachers would be lost

* * *

I do not imagine that there will be anything very fanciful about the objectives of any stage, nor anything very intricate about its organisation It is possible already to see the general outline in several schools, and I would imagine that our traditional respect for sound clinical method based on an uninterrupted introduction to it will result in most universities preferring not to bring clinical experience very far forward in the course Indeed one would expect the first stage to continue to be one of the study of the normal, based on the old preclinical departments together with new ones, such as genetics The preclinical departments already form a kind of stage committee in most schools, but the addition to it of clinical and other representatives would, without necessarily taking part in the teaching at all, go far to create that unity of purpose, common outlook, and single terminology at staff level, without which students' work will remain divided into preclinical and clinical

Later stages must of course continue to be based upon existing firms and departments, but the great strength of these will be fully utilised if all concerned know what they are trying to do For example, a stage devoted to practice of clinical method must obviously use general inpatient firms, but the teachers on these firms would not be left, as now, to try to grapple with all aspects of medicine, and would have instead agreed limited objectives together with a chance to assess their results Nor would they have to contend and compete with synchronous courses of instruction, of which neither the content nor the purpose was known to them

It is in the later part of the present clinical curriculum that confusion and dissipation of effort are now so marked, particularly in regard to the purposes of outpatient experience and the contribution of special departments Order can be created again out of near-chaos by this simple process of organising stages of learning and experience by groups of teachers responsible for them

* * *

Our peculiar system of hospital staff structure has provided us with a teaching device in the firm, which ensures that a small number of students are closely attached to a teacher who is personally responsible for them and for the patients with whom they are concerned The student is thus constantly reminded that the care of the individual patient is the yardstick by which everything else is measured He is able to learn of the professional responsibilities of a doctor by the only possible method—observing the doctor fulfilling them Above all, the welding together of his education and practical training is assisted by his being required to focus both his integrated knowledge and his practical skill upon the problems of his patients He is enabled to acquire empirical knowledge and experience and at the same time be encouraged to learn scientific method because his teacher can set him this example, can excite his curiosity, and can guide him as an individual through his personal difficulties of learning

It is small wonder that other countries are endeavouring to create for educational purposes this firm system which considerations of hospital practice developed here Unfortunately with us it has been weakened by many factors which we have not tried to offset The first of these is simply that the clinical teacher has not got the time which is required for the care of both his patients and his students The second is that we have continued to think of the firm as an inpatient organisation

I believe that part of the last clinical year should be devoted to a stage of learning by experience under supervision, and that this should be based on attachment, for at least four months to a general medical firm, primarily in the outpatient department but extending into the wards In this students should be responsible for individual patients as they now are on the traditional inpatient firm Student and patient together would visit the special departments as the patient's condition demanded, and both would return to the doctor responsible for both

At this stage it should also be easy to extend the student's experiences outside the walls of the hospital, to give him an understanding of the patient as a whole, and demonstrate the relation of medicine to the community It is here that I would incorporate the general practitioner into the undergraduate teaching team, with membership of the committee responsible for this stage, so that he is conversant with the objectives which the student has been set and with the lines on which his development is planned

* * *

The provision of a new curriculum and a new type of administration, however, will not completely solve the problem of readapting medical education to present conditions of medicine The inclusion into undergraduate medical schools of all that is meant by university education is also necessary An essential requirement of this is interest in the individual student, so that he may develop in a stimulating intellectual atmosphere, with the encouragement and guidance of his teachers It would be idle to pretend that this is now possible in all our schools

If the medical student is to be a university student, then he must be treated as such, and the medical school must provide not merely teachers, a curriculum of classes, and an administration, but also an educational service It is not enough to have a tutorial system which is a mere adjunct to the other forms of teaching The system providing encouragement and guidance must not be separate from the system of reproof, which is represented by authority and vested in the dean Any dichotomy can only result in resentment of authority or frustration of encouragement But if all good incentives are mobilised and coordinated into one discipline, then progressive assessment of the individual becomes possible, and he can be given such help as he is known to need The medical school must have some kind of director of studies as well as a dean—just as our older university colleges have a senior tutor as well as a master—tutors and supervisors as well as teachers

The increased need for education requires also a new attitude to halls of residence In many universities these have long been recognised as a means whereby students can educate themselves by indirect contact with several faculties In his later years, however, the medical student

However, all schools have been charged with the duty of adapting their education to meet modern conditions and needs, and most have already begun to do this

At first sight they appear to be up against an insuperable difficulty—that of deciding how much knowledge and how much training is to be in the undergraduate years, and how much in the postgraduate These questions seem difficult to answer in view of the fact that the responsibility for the postgraduate years is shared by the university with many other organisations, including the Royal Colleges and the Ministry of Health, and no one of them has sole authority Furthermore, nobody could at the moment be precise as to how much knowledge and how much technical skill is necessary for the minimum effective practice of any branch of medicine, particularly as the function of the family doctor is not yet clearly defined

But the fact that we do not know these things need not inhibit the reform of undergraduate education at all For the aim of this now, is first and foremost to *educate*—i e , to give the student *not* knowledge but the power to utilise knowledge

That he must know facts is obvious, and that in his early days he cannot find these out for himself but must be given them is equally obvious His and his teachers' primary purpose, however, must be that he learns how to learn for himself Therefore the factual content of the undergraduate period does not have to be any particular percentage of the total of medical knowledge, it has to be chosen for its relevance to future learning, not for its relevance to future practice Equally important, the student's progress must be assessed primarily on his ability to reason and utilise knowledge, and not merely in terms of the amount he knows Similarly his clinical proficiency must be judged on the soundness of his method, of which the correctness of the physical signs he elicits from a patient in an examination is but one indication By the same token, if it be true, as is sometimes claimed, that the newly qualified of today know more than their predecessors ever did, this does not mean that all is really well with medical education

If the object of undergraduate education is achieved, then gaps in knowledge and inadequacy of technique will be made good in the postgraduate period If the object of undergraduate education is not achieved, then such gaps will probably remain for ever, and he will be largely denied the mastery of new data and the critical evaluation of new treatment Though specialisation has come to stay, there is nothing the least static about the size or form of any particular specialty The future happiness and success of specialist and general practitioner alike depend on his ability to learn and on his knowledge of general principles

The following should be our objectives

1 The student must learn how to learn for himself

2 He must acquire a scientific method of thought—i e , the power to reason and think critically

3 He must achieve competence in clinical method—i e , the techniques of obtaining information from patients

4 He must gain an understanding of the responsibilities of a professional person

If these objectives are reached the student will inevitably have built up a foundation of knowledge, including empirical knowledge He will also have built a foundation of clinical experience, as regards the diagnosis, treatment, and prevention of disease on the one hand and the nature of man on the other The exact content of the foundations of knowledge and experience will vary, but during the years of his postgraduate training, each student will be able to fill in those gaps relevant to his own future practice

* * *

The undergraduate course of studies, thus freed from the need to include all or even any fixed percentage of knowledge and technique, can now, and must now, be based on considerations of the processes of learning

This granted, it is at once evident that many different arrangements of studies have much to commend them in theory Until they have been tried in practice, there can be no way of judging between them, and in any case the judgment can be no more than a clinical one It is therefore idle to speak of the curriculum as though there is somewhere a correct arrangement which will be correct for every school and every student The best curriculum for any particular school is that which enables it to make the best educational use of all its facilities and enables its students to progress through successive stages of learning, each with a clearly defined objective

The number and sequence of stages, together with the purpose and content of each, will vary from school to school, but there are certain requirements which must be met in every stage everywhere

1 Its purpose must be equally clear to both teachers and taught

2 There must be deployed in it those incentives to study which are relevant to that purpose

3 There must be built into it such forms of assessment of the student's progress as are appropriate to its content

It goes without saying that other objectives, contrary incentives, and inappropriate tests should be excluded as rigidly as possible

A course of studies of this kind cannot be made by a mere alteration of the timetable, even if this is done with educational objectives in mind An entirely new attitude to teaching is required, and reform of the curriculum will be ineffectual unless there is also a reform of the method by which the curriculum is devised, applied, and constantly assessed In my opinion this is no longer a matter of administration from the dean's office There is required for each stage of the course a team of men who are responsible for it They should represent all those departments most closely concerned with that stage, together with others whose advice could be helpful, even if they are not likely to teach in it themselves For example, preclinical teachers should be concerned with the planning and assessment of predominantly clinical stages, and clinicians with the predominantly preclinical stages

The team should, moreover, be representative of whole-time and part-time teachers, thus ensuring that the largest possible number of all kinds of teacher are closely involved in the educational effort In this way cooperation can be achieved, for, instead of every department competing for what it feels is its rightful portion of the student's time, each becomes more concerned with what it has to contribute to the common purpose of each stage of the student's development Furthermore, it is only when a teacher is able to appreciate the overall picture of that development that he can judge at what stage his own subject can make its best contribution At present the resources of a special department are often squandered because students are routed through it too early or too late Frequently also a student is able to attend a department for one period only, although it has something to offer him at several stages

The effective planning, execution, and frequent assessment of every stage of a real course of studies is quite beyond the capabilities of any dean's staff or curriculum committee, but every school could muster a team for each stage. Each team would be working towards a comprehensible and realisable objective, and would be able to define the content of knowledge and practical experience, deploy relevant incentives, and devise appropriate forms of assessment. If integration of staff were ensured, the student would be helped to integrate his knowledge for himself without the aid of elaborate timetable innovations—and neither the autonomy of departments nor the freedom of individual teachers would be lost.

* * *

I do not imagine that there will be anything very fanciful about the objectives of any stage, nor anything very intricate about its organisation. It is possible already to see the general outline in several schools, and I would imagine that our traditional respect for sound clinical method based on an uninterrupted introduction to it will result in most universities preferring not to bring clinical experience very far forward in the course. Indeed one would expect the first stage to continue to be one of the study of the normal, based on the old preclinical departments together with new ones, such as genetics. The preclinical departments already form a kind of stage committee in most schools, but the addition to it of clinical and other representatives would, without necessarily taking part in the teaching at all, go far to create that unity of purpose, common outlook, and single terminology at staff level, without which students' work will remain divided into preclinical and clinical.

Later stages must of course continue to be based upon existing firms and departments, but the great strength of these will be fully utilised if all concerned know what they are trying to do. For example, a stage devoted to practice of clinical method must obviously use general inpatient firms, but the teachers on these firms would not be left, as now, to try to grapple with all aspects of medicine, and would have instead agreed limited objectives together with a chance to assess their results. Nor would they have to contend and compete with synchronous courses of instruction, of which neither the content nor the purpose was known to them.

It is in the later part of the present clinical curriculum that confusion and dissipation of effort are now so marked, particularly in regard to the purposes of outpatient experience and the contribution of special departments. Order can be created again out of near-chaos by this simple process of organising stages of learning and experience by groups of teachers responsible for them.

* * *

Our peculiar system of hospital staff structure has provided us with a teaching device in the firm, which ensures that a small number of students are closely attached to a teacher who is personally responsible for them and for the patients with whom they are concerned. The student is thus constantly reminded that the care of the individual patient is the yardstick by which everything else is measured. He is able to learn of the professional responsibilities of a doctor by the only possible method—observing the doctor fulfilling them. Above all, the welding together of his education and practical training is assisted by his being required to focus both his integrated knowledge and his practical skill upon the problems of his patients. He is enabled to acquire empirical knowledge and experience and at the same time be encouraged to learn scientific method because his teacher can set him this example, can excite his curiosity, and can guide him as an individual through his personal difficulties of learning.

It is small wonder that other countries are endeavouring to create for educational purposes this firm system which considerations of hospital practice developed here. Unfortunately with us it has been weakened by many factors which we have not tried to offset. The first of these is simply that the clinical teacher has not got the time which is required for the care of both his patients and his students. The second is that we have continued to think of the firm as an inpatient organisation.

I believe that part of the last clinical year should be devoted to a stage of learning by experience under supervision, and that this should be based on attachment, for at least four months to a general medical firm, primarily in the outpatient department but extending into the wards. In this students should be responsible for individual patients as they now are on the traditional inpatient firm. Student and patient together would visit the special departments as the patient's condition demanded, and both would return to the doctor responsible for both.

At this stage it should also be easy to extend the student's experiences outside the walls of the hospital, to give him an understanding of the patient as a whole, and demonstrate the relation of medicine to the community. It is here that I would incorporate the general practitioner into the undergraduate teaching team, with membership of the committee responsible for this stage, so that he is conversant with the objectives which the student has been set and with the lines on which his development is planned.

* * *

The provision of a new curriculum and a new type of administration, however, will not completely solve the problem of readapting medical education to present conditions of medicine. The inclusion into undergraduate medical schools of all that is meant by university education is also necessary. An essential requirement of this is interest in the individual student, so that he may develop in a stimulating intellectual atmosphere, with the encouragement and guidance of his teachers. It would be idle to pretend that this is now possible in all our schools.

If the medical student is to be a university student, then he must be treated as such, and the medical school must provide not merely teachers, a curriculum of classes, and an administration, but also an educational service. It is not enough to have a tutorial system which is a mere adjunct to the other forms of teaching. The system providing encouragement and guidance must not be separate from the system of reproof, which is represented by authority and vested in the dean. Any dichotomy can only result in resentment of authority or frustration of encouragement. But if all good incentives are mobilised and coordinated into one discipline, then progressive assessment of the individual becomes possible, and he can be given such help as he is known to need. The medical school must have some kind of director of studies as well as a dean—just as our older university colleges have a senior tutor as well as a master—tutors and supervisors as well as teachers.

The increased need for education requires also a new attitude to halls of residence. In many universities these have long been recognised as a means whereby students can educate themselves by indirect contact with several faculties. In his later years, however, the medical student lingers on after his colleagues in other disciplines and tends to become more attached to a hospital than a university. Those who have no home in the vicinity may live in a hostel belonging to the medical school, but such hostels, as their name implies, are often thought of as merely lodging-houses conveniently near the wards. There is a great need for a change of attitude so that these places can play their full part in education. All students should spend some time in them, and not merely those who have difficulty in finding accommodation elsewhere. Far greater responsibility for the corporate life of the student body should then be given to the students themselves—a necessary experience for those who are going to carry heavy professional burdens but who now tend to be kept from both responsibility and community life up to the age of 24. In this field also the teaching staff have a large part to play, not as persons of authority or with administrative duties, but as senior members of a single professional and intellectual community.

In none of these things, which I believe to be so important, do I envisage any kind of spoon-feeding or wet-nursing of students. On the contrary, I am advocating that they be regarded much less as groups of overgrown schoolboys, and much more as individual adult members of a profession. Their reactions to the education offered must be regularly sought, as in most other countries it now is, and they should feel free to seek advice on problems of learning without fear of jeopardising their careers. In the past medical schools have been so concerned with teaching and examinations, that few facilities, either material or in personnel, now exist for education. The need for them is urgent, and they are required for the postgraduate as well as the undergraduate. The days have passed when any medical school can feel that its responsibility for a man has ended when he has passed his final examinations.

" Finals ", of course, are now a misnomer, for they merely indicate a qualification which is necessary before the student is in his last year of general internship, legally able to undertake the responsible practice under supervision of which this stage of experience is composed. It remains to be seen whether this stage should be increased in duration or advanced in time. But it is already a responsibility of the medical schools, though not one which they have been able fully to discharge. They will need to develop a much more active system of caring for the individual before they can do so.

It will only be when such a system has developed that many other features of a university education in medicine can be properly undertaken. For example electives, and opportunities for students to study a subject in depth by undertaking some piece of original work, depend for their full effect on adequate knowledge and guidance of the individual. Furthermore we have to regain in this country greater freedom for each student to develop in his own way and at his own speed. We have had an overcrowded curriculum for so long, that we have almost come at accept the idea of having the same timetable for every student. Worse still, the system of grants, by which most students are financed, has encouraged the idea, in both medical schools and grant-giving authorities, that there is a fixed maximum duration of studies which is properly common to all students. This is most unfortunate, because no-one has ever laid down more than a minimum period, and students do not all progress at the same speed. It is an odd paradox that by so rightly removing financial barriers to medical education in this country, we have at the same time removed from the individual his necessary freedom to vary from the average. In the United States where most students are privately financed, it is easier for a man to step off the production-line than it is here, where courses are repeated only by students who have done badly. In Sweden, where students can get State loans but not grants, the finishing line is an entirely personal affair. Our system of a class of students all taking their examination on the same day is regarded as most unusual.

* * *

In my view readaptation of medical education depends then, on (1) a course of studies, based on stages of learning together with relevant forms of assessment, (2) a more effective method of operating and maintaining the new curriculum, and (3) a university atmosphere. If these three things are provided, then undoubtedly new teaching techniques will emerge, or at all events we shall learn much more than we now know about the problems of education and the answers to them. In order to set our house in order, however, we do not need any more information than we now have. It is as useless as it is dangerous to wait for scientific proof that this or that is necessary, or that one scheme is better than another. This is a matter for clinical judgment. It is futile, and really only a form of escapism, to wait for some magic concrete plan which can be put into administrative effect and then forgotten.

The main obstacle to the full implementation of these three things is that very few teachers have enough time in which to give undivided attention to education. This can be remedied only by ensuring that part-time clinical teachers particularly, have enough sessions at the teaching hospital to enable them to practise clinical medicine, educate students, and engage in research. It is essential that this is done, if the country is to continue to have a high standard of medical service. It will inevitably cost money, but medical education is important. It alone can pass the advances of medicine on into effective practice. It is hopeless and wasteful to tackle it halfheartedly, and the most economical medical school, like the most economical hospital, is the one which sets out to be the best rather than the cheapest.

If in the National Health Service we can but make the terms and conditions of service of medical teachers relevant to the demands of education, we shall be able to mobilise a quite remarkable number of assets. Indeed, we should be in a far better position than any other country to solve the remaining problems of medical education.

* * *

It seems justifiable to expect, therefore, that after a long period of difficulty, we can now enter a period in which medical education will be once more in equilibrium with medicine. Certainly we should be able most successfully to give an education in medicine while retaining and even improving our ability to teach sound clinical method. But this does not mean that we will then be automatically giving a good preparation for medicine as a profession.

The basis of British practice is that each patient, whether in his home or at hospital, has one doctor who takes personal responsibility for him, but there is no doubt that this basis has been weakened, and that too often there is uncertainty as to who is really responsible for the patient. The doctor also has a responsibility to the community, which cannot be discharged merely by attending to individuals, and students have to be made aware of very many important duties of the profession other than that of diagnosing and treating disease. Lastly we have, always, the problem of the way in which we discharge our duties—the standard which the profession sets for itself and the nature of its corporate discipline.

In times of great change the standards of a profession are at risk, and all ethics have to be translated into new terms. Moral exhortation without content or direction is a futile thing, and today the student must be brought to share the problems which face his teacher both as concern the patient and the profession. He must learn that science, which he must use, searches only after truth and has no humanitarian ends in view; but he must also learn that in a *professional* community, unlike others, how a decision is made is more important than what is decided.

These problems are difficult—but only because medicine and the profession face a greater challenge than ever before. I would say that there has never been a better time than this in which to be a doctor: the opportunities, like the challenge, are greater than ever before. They are greater, I believe, in this country than in any other: we are in a better position to solve all our problems. But we cannot do so unless we set our sights high. We must accept that in a time of change the most idealistic approach is the most realistic. The pursuit of quality is the only aim proper to our profession and the only one it can afford to have.

THE EFFECT OF TEST FEEDS ON THE PLASMA LIPIDS

K. J. KINGSBURY
M.B., Ph.D. Lond.
SENIOR LECTURER

D. M. MORGAN
RESEARCH ASSISTANT

P. C. SHERRINGTON
RESEARCH ASSISTANT

THE SURGICAL UNIT, ST. MARY'S HOSPITAL, LONDON, W.2

It has been shown repeatedly that the type of fat in the diet affects the lipid content of the plasma. But the kind of investigation so far reported has several disadvantages.

The lipid changes have been produced by feeding particular oils and fats for several days, weeks, or even months, with the remainder of the diet under careful control; and in these circumstances several weeks elapse before the plasma lipids reach a constant level on the basal diet and again with each fat under test. Because during all this time the basal diet has to be rigidly controlled (Ahrens et al. 1957), many investigators have resorted to giving this diet as homogenised liquid feeds (Kinsell et al. 1953). Apart from the practical difficulties—especially for studies on normal people and outpatients—arising from long-continued control, the test materials may not be available in sufficient quantity, or may be unsuitable for long-term administration (e.g., tung oil). Moreover the effects of trace materials, and the relative importance of particular substances, are often difficult to evaluate when whole diets are being fed.

Hence, for identifying and defining the dietary factors that influence human lipid metabolism, there is need of a quick and reproducible biological test. This should last no more than 12 hours, for then only the test substance need be fed, the experimental conditions can be easily controlled, and any lipid changes can be compared with the effects of fasting for an equal period. Also, if the test is to be used as a method of biological assay, it should evoke reproducible responses in normal people and be sensitive to small changes.

Such a method, in this laboratory, has been in use for 4 years. Single test feeds of oils are given under standard conditions so that the effect of each oil on the plasma lipids can be quickly and clearly demonstrated. In this paper we illustrate the method first by describing the effect of arachis oil on the plasma glyceride, phospholipid, and cholesterol, and then by reporting the effects of various other oils.

Materials and Methods

The subjects were healthy male medical students (aged 19–33) on the same kind of diet and activity. They were not allowed dietary fat during the 12 hours before the experiment nor excessive fat on the previous day, and their fasting plasma was clear. A light breakfast of fat-free drinks, dry toast, and marmalade was allowed 2–3 hours before the experiment.

The Test Feed

50 g. of the oil is given as a single feed, emulsified with 50 ml. of skimmed milk and 50–100 ml. of tap water, and flavoured if desired. (With feeds of less than 30 g. the changes in the plasma lipids are small and inconsistent, while feeds above 60–70 g. often cause nausea without proportionately increasing the plasma-lipid changes.) The emulsions must not be oily or thick and should be at room temperature; they should be drunk quickly, without breathing through the nose. The feeds are followed immediately by a strong-tasting drink, such as blackcurrant cordial, and by an apple.

A standard procedure without unpleasantness is essential, for, if the subjects are nauseated, the absorption of the feed is apparently delayed and the plasma-lipid changes are prolonged and inconsistent.

Collection of Blood Samples

Samples were taken before the feeds, and at 1½, 3½, 5½, 7–9, and 24 hours after them. The blood was obtained by venepuncture using siliconed syringes and run into 3.8% sodium-citrate solution buffered to pH 7.4 (18 ml. of blood to 2 ml. citrate solution); the plasma was separated immediately by centrifuging and then stored at 4°C. The analyses were begun next day.

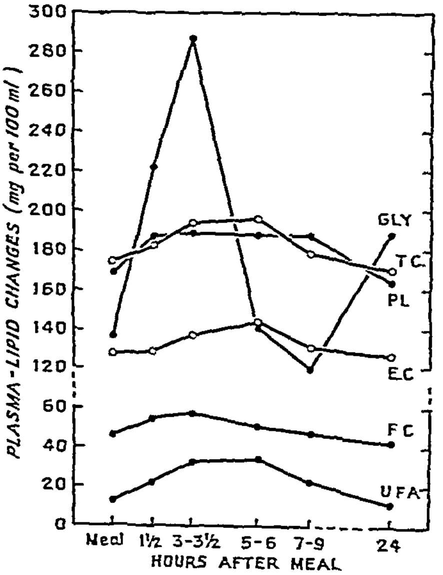

Fig. 1—The plasma-lipid levels before and after the 50 g. meals of arachis oil (mean of six results).

GLY, glycerides; T.C., total cholesterol; PL, phospholipids; E.C., esterified cholesterol; F.C., free cholesterol; U.F.A., unsaturated fatty acids.

Methods of Analysis

Lipid phosphorus was determined by the method of Fiske and Subbarow (Hawk et al. 1947), total and free cholesterol by that of MacIntyre and Ralston (1954), unesterified fatty acids according to Grossman et al. (1954), and plasma total esterified fatty acids by the method of Morgan and Kingsbury (1959).

The entire series of plasma samples from each individual, plus the various standards, were analysed together in triplicate. In this way fine differences between samples could be recognised. The coefficient of variation of replicate samples by each method has always been less than 0·8%. Total-cholesterol or *phospholipid changes of more than 3 mg. per 100 ml.* between the samples of one run, have therefore been accepted as significant.

Effects of Arachis Oil

After single feeds of 50 g. arachis oil the first observed change in the plasma lipids was an increase of glycerides, which reached a maximum 3–$3^{1}/_{2}$ hours after the feeds, after which the values fell rapidly for 3 hours and then more slowly and variably. This increase in glycerides was accompanied by a slower rise and fall of the plasma cholesterol, phospholipids, and unesterified fatty acids, which reached their maximum at 3–6 hours after the meals, decreased gradually in the next 3 hours, and then fell very slowly. The amount and the timing of the cholesterol and phospholipid changes were very similar. The behaviour of the plasma lipids is shown in fig. 1, which gives the average values obtained in six volunteers.

It has been found that if too little of the oil is absorbed, or if the oil is absorbed too slowly, the subsequent changes in the cholesterol and phospholipids are inconsistent and unpredictable. Adequate absorption of the oil, normally timed, is therefore a necessary condition of the experiment, and we do not consider it adequate unless the plasma glycerides rise between the fasting and $3^{1}/_{2}$-hour samples and fall between the $3^{1}/_{2}$-hour and $5^{1}/_{2}$-hour samples. Thus, if the plasma glycerides had not increased by more than 60 mg. per 100 ml. plasma (0·7 mMol. per litre) at $3^{1}/_{2}$ hours, and if over a third of this increase had not been removed by $5^{1}/_{2}$ hours, the experiment was rejected. The glyceride increases shown in our results represent, therefore, the differences between the fasting and $3^{1}/_{2}$ hour samples, and the percentage clearances are the percentage removal of these increases between $3^{1}/_{2}$ hours and $5^{1}/_{2}$ hours.

In normal subjects with a clear fasting plasma and a

PL. = Phospholipids T.C. = Total cholesterol F.C. = Free cholesterol E.C. = Esterified cholesterol U.F.A. = Unsaturated fatty acids

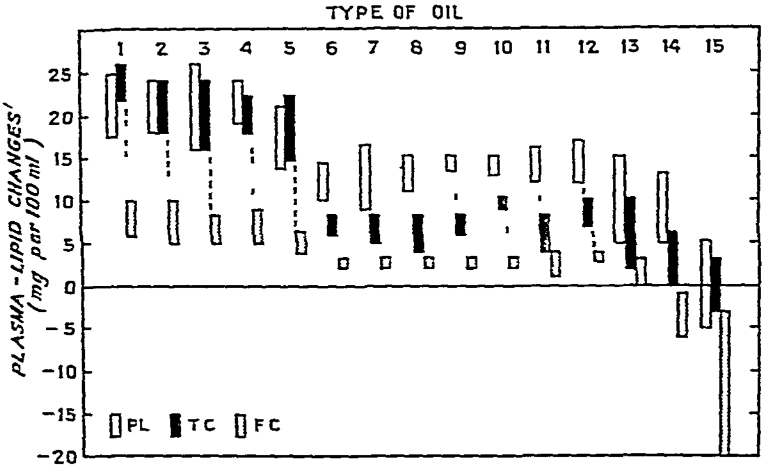

Fig 2

Fig 2—The changes in plasma phospholipid and cholesterol caused by the various oils (numbered as in table)

The effects of fractions A and B, cod-liver oil and of fasting, shown in the table are, for the sake of simplicity, not included in the figure.

PL.=phospholipids, T.C.=total cholesterol, F.C.=free cholesterol

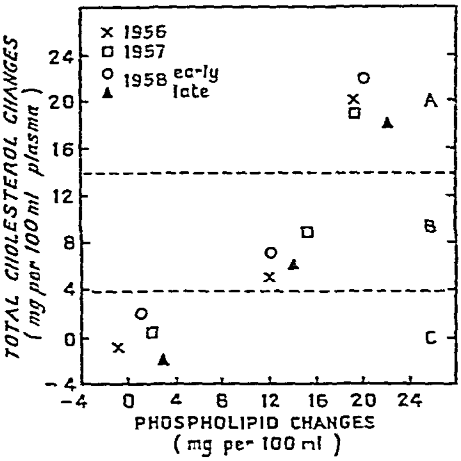

Fig 3

Fig 3—The response of three subjects to the same test feed when fed at intervals over 3 years

A, arachis, B, heated tobacco-seed oil, C, crude tobacco-seed oil

The fasting plasma levels of the three subjects were A, phospholipids 98 mg per 100 ml, total cholesterol 235 mg, B, phospholipids 158 mg, total cholesterol 169 mg, C, phospholipids 222 mg, total cholesterol 254 mg

normal absorption of glyceride, plasma cholesterol and phospholipid reached their maximum 3–6 hours after the feed. The changes in phospholipids and cholesterol caused by the feeds can be expressed by the values

$$\frac{(3^{1/2}\text{ hour}-\text{fasting})-(5^{1/2}\text{ hour}-\text{fasting})}{2}$$

The figure obtained in this way we call the lipid response.

Effects of Various Other Oils

Single 50 g feeds of other oils were fed in the same way to normal volunteers The oils used, the number of experiments, and the lipid response are shown in the table.

Non-polymerised refined tung oil was supplied by Unilever Co The other oils were of edible grade and obtained from Unilever Co, H M Faure & Co, British Cod Liver Oils Ltd, and through Hess Products and Cyclo Chemicals Ltd

Stored tobacco-seed oil is crude oil which has been stored at 4 C in the dark for 9 months and 'heated tobacco-seed oil' is the crude oil heated by steam to 165 C under a high vacuum

Fraction A' and "fraction B were prepared from the fatty acids obtained by dehydrating ricinoleic acid Those liquid below 10 C (Hilditch 1956) were stored at 0 C for several weeks in the dark in an atmosphere of nitrogen, a solid fraction was separated by filtration at 0 C Both liquid and soil fractions were then frozen at 20 C, stored at 0 C for several weeks, and filtered as before The fractions solid at 0 C were combined and called fraction A, the combined fractions were called fraction C They were fed as ethyl esters

With all the oils, plasma glyceride rose by more than 60 mg per 100 ml and over a third of this increase was removed at $3^1/_2$–$5^1/_2$ hours But the different oils produced three different types of lipid response, and can accordingly be placed in three groups (table and fig 2)

Group 1—These raised the total-cholesterol and phospholipid levels by about 20 mg per 100 ml., without altering the ratios of total cholesterol to phospholipid or of free cholesterol to esterified cholesterol.

Group 2—The increases in total cholesterol and phospholipid were smaller, but the ratio of total cholesterol to phospholipid was reduced. The ratio of free cholesterol to esterified cholesterol was unaltered.

Group 3—With the oils in this group (crude and stored tobacco-seed oil) the levels of phospholipid and total cholesterol rose only very slightly or actually *fell* The level of free cholesterol consistently fell, but both the phospholipid and the free-cholesterol/esterified-cholesterol ratios were variable.

These different lipid responses were not associated with differences in the amounts of glyceride increase

In control experiments a fat-free diet, taken for 24 hours, reduced the levels of all the plasma lipids estimated.

Reproducibility of Lipid Response

Fig 3 shows the changes in cholesterol and phospholipid levels obtained with oils of the three groups Each volunteer received one oil four times, and on each occasion it produced the same kind of response, distinct from the effects of the other oils In the experiment recorded in fig 4, each of four volunteers took three different oils All four subjects showed the same type of lipid response to a given oil, and similar alterations in response when the oils were changed. (In fig 4, for simplicity, only the cholesterol changes are shown.)

Thus healthy people gave the same lipid response to a particular type of oil, even when the tests were separated

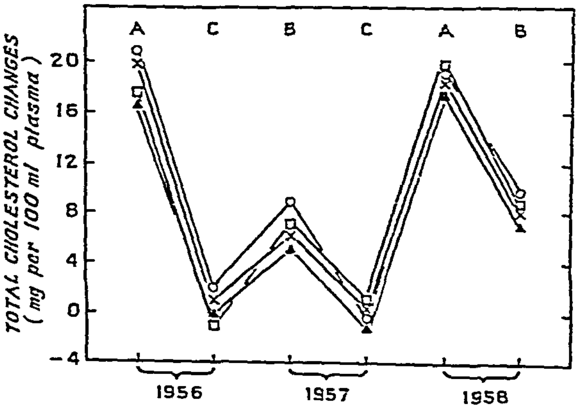

Fig 4—The "swing" of response in four subjects to three different types of oil (A, arachis B heated tobacco-seed oil C, crude tobacco-seed oil)

The fasting levels of total cholesterol in the four subjects were X, 181 mg per 100 ml, □, 211 mg ○ 183 mg, ▲, 189 mg by a year, and, by changing the oil, the volunteers could be "swung" to another response Clearly, the reproducibility of the results was not due to insensitiveness of the test This could in fact distinguish between the effects not only of different oils but even of the same oil before and after treatment by heat (table and fig 2)

Discussion

As a method of biological assay, the test feed has the advantage of simplicity, speed, and ease of control, and it enables us to ascertain the effects of single substances, using comparatively little material Their effects on plasma lipids are demonstrated not only (as in the longer experiments) by the changes in cholesterol and phospholipid but also by the relation of these lipids to one another and the relation of free cholesterol to esterified cholesterol The alterations in these relations are new findings which suggest that plasma-phospholipid and plasma-cholesterol levels are under separate physiological control Even in normal people the phospholipid/cholesterol ratio is not necessarily constant, and its different behaviour in response to group-1 and group-2 oils raises the interesting question whether it is ordinarily set by the diet

The different effects of crude and heated tobacco-seed oils is a further new finding, which will be discussed elsewhere The difference does not seem to be due to alterations in the fatty-acid composition of the oils

It is difficult to compare our results with those of other workers who have used single feeds for studying changes in the plasma lipids (Man and Gildea 1932, Lindholm 1956, Dole et al 1959), for, although Man and Gildea, for example, recorded similar phospholipid changes, their aim was to see whether lipid changes did in fact occur, and not to create a standard method of biological assay (Kingsbury 1958) Reasons why our findings may differ from those of the longer (more usual) experiments are numerous

1 The oils may have been subjected to different treatment (compare our different results with crude and heated tobacco-seed oils)

2 Most of the other work has been done on patients, whereas ours was on normal subjects

3 The results reported here concern only the period of lipid increase immediately following the fatty meals, whereas the results of long-term experiments must be the algebraic sum of varying lipid absorption, plasma-lipid increases, and clearance of lipids from the blood

4 The two methods may be sensitive to different variables

5 Whereas our results describe changes from a standard basal condition, the changes in the long-term experiments result from altering one diet for another This point can be illustrated by the fact that in the long experiments corn oil has so often caused an immediate and progressive fall in the plasma-cholesterol level, whereas in our experiments it caused a rise

It is all the more interesting, therefore, that our results should in many ways resemble those of Ahrens (1957), using the longer method In both investigations oils having iodine values above 100 produced low levels of plasma cholesterol, whereas with oils which have iodine values below 90 the cholesterol level increased with the saturation of the fat (see table) Whale, pilchard, and cod-liver-oil—which are rich in polyunsaturated acids but not in those essential for the normal health of animals (Thomasson 1953)—gave the same kinds of lipid responses as the edible vegetable oils (corn, soya, sunflower) whose high content of unsaturated acids is composed mainly of "essential" fatty acids This is similar to the results of Ahrens (1959)

In view of the similar effect of fish oils and vegetable oils on the plasma-cholesterol, it is interesting to reflect that, though an increase of tri-unsaturated acids in the tissue lipids of animals is strong evidence for a deficiency of the essential fatty acids (Jorgensen and Holman 1958), this accumulation of trienes has been reversed by cod-liver oil (Rieckenhoff et al 1949, Dam et al 1959), and that though this oil is rich in polyunsaturated acids, it has a very low essential-fatty-acid activity when assessed conventionally in terms of a normal skin in animals Thus it seems that many of the polyunsaturated acids, such as those found in cod-liver oil, may not only lower the blood-cholesterol level but also correct fatty-acid deficiencies

As conventionally defined, a "non-essential" acid very similar in physical properties to the "essential" linoleic acid is its *cis-trans* isomer, which has a melting-point of about −3°C (Privett et al 1955) or up to 7°C (Jackson et al 1952) Unfortunately it cannot yet be made in quantities sufficient for feeding experiments, but, as an alternative, we hoped to obtain low-melting-point isomers of linoleic acid from dehydrated ricinoleic acids (Hilditch 1956) Ultraviolet spectroscopic analysis (Hilditch et al 1951) of our fractions A and B showed that about 60% were linoleic acid or its isomers, of which about half were conjugated, probably the *cis-trans* isomers were concentrated in fraction B (melting-point 0–10°C) As both these fractions raised the plasma lipids only slightly (see table) it appeared that the lipid response to the natural *cis-cis* linoleic acid (approximately 70% of tobacco-seed oil) was neither prevented nor obscured by its conjugated or other isomers

Our results with tung oil are not at present explainable Sinclair (1959) has suggested that it should have the same effects as other non-essential oils of equal unsaturation, but this ignores its undoubtedly different properties, as evident in its chemical reactivity, rate of oxidation, and absorption spectra in the ultraviolet Possibly the biological action of conjugated fatty acids of this type differs from that of non-conjugated acids of equal unsaturation

The reasons for the different effects of the various oils are not yet established, but we cannot see why many factors in oils should not act in different ways For instance, the amount of the biologically essential linoleic acid usually given as a dietary supplement is about 50 g a day (Olson et al 1958) This would be about 5–10% of the total dry weight of the daily diet of our volunteers and probably about 10% of a patient's hospital diet In animals, however, severe essential-fatty-acid deficiency can be corrected by less than 0 5% of linoleic or arachidonic acid in the diet (Holman 1950)—an amount of arachidonic acid which is said to have no effect on the plasma lipids of man (Keys et al 1959) It may be that, in large amounts, unsaturated acids (both essential and non-essential) alter the physicochemical properties and hence the metabolism of their esters (glycerides, cholesterols, phospholipids, &c) (Klein and Martin 1959) This need not exclude a simultaneous correction of any existing fatty-acid deficiency (Fulco and Mead 1959)

In addition, an effect from the non-saponifiable or trace components of an oil cannot be excluded, and this may be the reason why crude tobacco-seed oil and heated tobacco-seed oil (though we have found no difference in their fatty-acid composition) have different effects

by a year, and, by changing the oil, the volunteers could be " swung " to another response Clearly, the reproducibility of the results was not due to insensitiveness of the test This could in fact distinguish between the effects not only of different oils but even of the same oil before and after treatment by heat (table and fig 2)

Discussion

As a method of biological assay, the test feed has the advantage of simplicity, speed, and ease of control, and it enables us to ascertain the effects of single substances, using comparatively little material Their effects on plasma lipids are demonstrated not only (as in the longer experiments) by the changes in cholesterol and phospholipid but also by the relation of these lipids to one another and the relation of free cholesterol to esterified cholesterol The alterations in these relations are new findings which suggest that plasma-phospholipid and plasma-cholesterol levels are under separate physiological control Even in normal people the phospholipid/cholesterol ratio is not necessarily constant, and its different behaviour in response to group-1 and group-2 oils raises the interesting question whether it is ordinarily set by the diet

The different effects of crude and heated tobacco-seed oils is a further new finding, which will be discussed elsewhere The difference does not seem to be due to alterations in the fatty-acid composition of the oils

It is difficult to compare our results with those of other workers who have used single feeds for studying changes in the plasma lipids (Man and Gildea 1932, Lindholm 1956, Dole et al 1959), for, although Man and Gildea, for example, recorded similar phospholipid changes, their aim was to see whether lipid changes did in fact occur, and not to create a standard method of biological assay (Kingsbury 1958) Reasons why our findings may differ from those of the longer (more usual) experiments are numerous

1 The oils may have been subjected to different treatment (compare our different results with crude and heated tobacco-seed oils)

2 Most of the other work has been done on patients, whereas ours was on normal subjects

3 The results reported here concern only the period of lipid increase immediately following the fatty meals, whereas the results of long-term experiments must be the algebraic sum of varying lipid absorption, plasma-lipid increases, and clearance of lipids from the blood

4 The two methods may be sensitive to different variables

5 Whereas our results describe changes from a standard basal condition, the changes in the long-term experiments result from altering one diet for another This point can be illustrated by the fact that in the long experiments corn oil has so often caused an immediate and progressive fall in the plasma-cholesterol level, whereas in our experiments it caused a rise

It is all the more interesting, therefore, that our results should in many ways resemble those of Ahrens (1957), using the longer method In both investigations oils having iodine values above 100 produced low levels of plasma cholesterol, whereas with oils which have iodine values below 90 the cholesterol level increased with the saturation of the fat (see table) Whale, pilchard, and cod-liver-oil—which are rich in polyunsaturated acids but not in those essential for the normal health of animals (Thomasson 1953)—gave the same kinds of lipid responses as the edible vegetable oils (corn, soya, sunflower) whose high content of unsaturated acids is composed mainly of " essential " fatty acids This is similar to the results of Ahrens (1959)

In view of the similar effect of fish oils and vegetable oils on the plasma-cholesterol, it is interesting to reflect that, though an increase of tri-unsaturated acids in the tissue lipids of animals is strong evidence for a deficiency of the essential fatty acids (Jorgensen and Holman 1958), this accumulation of trienes has been reversed by cod-liver oil (Rieckenhoff et al 1949, Dam et al 1959), and that though this oil is rich in polyunsaturated acids, it has a very low essential-fatty-acid activity when assessed conventionally in terms of a normal skin in animals Thus it seems that many of the polyunsaturated acids, such as those found in cod-liver oil, may not only lower the blood-cholesterol level but also correct fatty-acid deficiencies

As conventionally defined, a " non-essential " acid very similar in physical properties to the " essential " linoleic acid is its *cis-trans* isomer, which has a melting-point of about −3°C (Privett et al 1955) or up to 7°C (Jackson et al 1952) Unfortunately it cannot yet be made in quantities sufficient for feeding experiments, but, as an alternative, we hoped to obtain low-melting-point isomers of linoleic acid from dehydrated ricinoleic acids (Hilditch 1956) Ultraviolet spectroscopic analysis (Hilditch et al 1951) of our fractions A and B showed that about 60% were linoleic acid or its isomers, of which about half were conjugated, probably the *cis-trans* isomers were concentrated in fraction B (melting-point 0–10°C) As both these fractions raised the plasma lipids only slightly (see table) it appeared that the lipid response to the natural *cis-cis* linoleic acid (approximately 70% of tobacco-seed oil) was neither prevented nor obscured by its conjugated or other isomers

Our results with tung oil are not at present explainable Sinclair (1959) has suggested that it should have the same effects as other non-essential oils of equal unsaturation, but this ignores its undoubtedly different properties, as evident in its chemical reactivity, rate of oxidation, and absorption spectra in the ultraviolet Possibly the biological action of conjugated fatty acids of this type differs from that of non-conjugated acids of equal unsaturation

The reasons for the different effects of the various oils are not yet established, but we cannot see why many factors in oils should not act in different ways For instance, the amount of the biologically essential linoleic acid usually given as a dietary supplement is about 50 g a day (Olson et al 1958) This would be about 5–10% of the total dry weight of the daily diet of our volunteers and probably about 10% of a patient's hospital diet In animals, however, severe essential-fatty-acid deficiency can be corrected by less than 0 5% of linoleic or arachidonic acid in the diet (Holman 1950)—an amount of arachidonic acid which is said to have no effect on the plasma lipids of man (Keys et al 1959) It may be that, in large amounts, unsaturated acids (both essential and non-essential) alter the physicochemical properties and hence the metabolism of their esters (glycerides, cholesterols, phospholipids, &c) (Klein and Martin 1959) This need not exclude a simultaneous correction of any existing fatty-acid deficiency (Fulco and Mead 1959)

In addition, an effect from the non-saponifiable or trace components of an oil cannot be excluded, and this may be the reason why crude tobacco-seed oil and heated tobacco-seed oil (though we have found no difference in their fatty-acid composition) have different effects

Summary and Conclusions

A method for the biological assay of dietary lipids is described in which changes in the plasma glycerides, cholesterol, and phospholipids are measured after single 50 g. feeds of the fat under investigation. Plasma samples are collected before and 1½, 3½, 5½, 7–9, and 24 hours after the test feed.

The conditions for success are a period of fat deprivation and a clear fasting plasma before the experiment, a standard method of feeding, the avoidance of nausea, and adequate absorption of the oil. The criterion of adequate absorption is a rise in plasma glycerides by more than 60 mg. at 3½ hours, of which increase over a third must have been removed by 5½ hours.

The plasma-cholesterol and plasma-phospholipid changes produced by the feeds are called the lipid response. This response differs with different oils, the characteristic changes being reproducible both in different subjects and in the same subjects after long intervals.

The method has the advantage of needing only small amounts of material, of being quick and sensitive, of easily allowing experimental controls, and of not requiring special diets.

It is not offered as an alternative to long-term experiment, but as a supplementary method especially useful for rapid biological assays.

New contributions by this method are (1) the finding that different oils have different effects on the plasma phospholipid cholesterol ratios, (2) the use of these changing ratios to classify the type of lipid response to the experimental fat, and (3) the different effects of crude and heated oils.

The reasons for the different effects of the various oils are not known, but they are unlikely to be all due to one type of substance or property.

We wish to thank the volunteers, without whom the work would have been impossible and who received no recompense for much unpleasantness, Mr W. Darrel and Mr P. A. Dupont for technical assistance, Prof. C. G. Rob and Mr R. W. Best (Unilever Ltd.) for advice and interest, and Bush & Co. for generous gifts of flavourings. Part of this work was included by K. J. K. in a thesis for the degree of doctor of philosophy, London University, 1958.

MYOCARDIAL INFARCTION AMONG MEMBERS OF COMMUNAL SETTLEMENTS IN ISRAEL

DANIEL BRUNNER
M.D. Vienna

GIDEON MANELIS
M.D. Geneva

From the First Medical Department and Research Laboratory for Degenerative Cardiovascular Diseases, Government Hospital, Jaffa, Israel

THE incidence of ischæmic heart-disease differs strikingly between different countries (World Health Organisation 1956) and even in a single country between different ethnic and social groups (Brock and Bronte Stewart 1955, Brunner and Löbl 1957, 1958, Dreyfuss 1953, Toor et al. 1957).

We have sought to examine the influence of physical exercise on the incidence of myocardial infarction in the Kibbutzim and Kvutzoth. These are communal settlements in Israel, whose members are ethnically homogeneous and where the environmental conditions (standard of living, diet, housing, cultural activity, and recreation) are virtually uniform. No difference is made between teachers, clerks, businessmen, local political leaders, drivers, fishermen, masons, and agricultural workers.

Material and Methods

This survey covers the incidence of myocardial infarction in the ten years up to Dec. 31, 1959, in 8500 people (4500 men and 4000 women) who at the end of 1949 were aged 30–55.

One of us (G. M.) visited each of the 58 settlements in which these people lived. Because of the comprehensive medical service in these settlements, we had no difficulty in obtaining data on all fatal cases (sickness certificates, hospital case-records, postmortem reports, and electrocardiograms) and surviving patients who had had myocardial infarcts (detailed clinical examination and electrocardiograms). All patients except 2 were admitted to hospital soon after the infarction. Thus the diagnosis of myocardial infarction, whether the patient survived or died, was based on the clinical picture and on an unequivocal electrocardiographical diagnosis. As electrocardiographic proof of myocardial infarction we accepted only typical Q waves or typical T waves, or both together. Not included in this review are patients who presented the clinical picture of angina pectoris with or without the electrocardiographic pattern of coronary insufficiency.

Findings

In the ten-year period there occurred, among the population of 8500, 111 cases of myocardial infarction; 34 patients died and 77 survived. Of the 4000 women, only 9 had infarction, and of these 2 died and 7 survived.

In the communal settlements of all persons in the age-group of the sample, 30% are engaged in sedentary work and 70% in non-sedentary work. By contrast, in the cases of myocardial infarction, of the 34 who died 19 were engaged in sedentary work, and, of the 77 who survived, 42 were engaged in sedentary work. The group of non-sedentary workers included also those doing very light bodily work, such as that of confectioner or light physical work in industrial factories. When classifying the men according to their occupation, we took into account work done by the patient for at least four years before the attack. Particular care was taken not to include in this or any other group men who had changed their occupation as a result of their illness.

For non-sedentary male workers the annual incidence was 1.36 per 1000, whereas for sedentary male workers the annual incidence was 4.1 per 1000. Thus the incidence was three times greater in the sedentary workers. The

mortality-rate was likewise three times greater in this group

Comment

These data support those of Morris (Morris et al 1953, Morris and Crawford 1958) indicating the preventive influence of bodily activity

Jewish people are reputedly especially prone to ischæmic heart-disease (Epstein et al 1957), but our findings do not support this belief The annual incidence of myocardial infarction among the sedentary Jewish workers whom we studied is almost identical with that in London sedentary workers observed by Morris et al (1953) On the other hand, the incidence of myocardial infarction among non-sedentary workers in Kibbutz (0 8 per 1000 men per year) is only half the incidence among London postmen who walked in their daily work (1 6 per 1000 men per year)

These findings underline the importance of physical exercise as a factor in the prevention of myocardial infarction

This research was carried out with the aid of a grant from the Fund for Applied Research of the Israeli Ministry of Health and from the Research Foundation of the General Federation of Jewish Labour in Israel (Histadruth)

From the Department of Internal Medicine B, and Department of Ophthalmology, Rothschild Hadassah University Hospital, Jerusalem, Israel

INDIRECT evidence, based on hospital statistics, has shown that arteriosclerotic cardiovascular disease is more common among the Yemenite community who have lived in Israel for a long time than among new immigrants from Yemen (Dreyfuss 1953, Toor et al 1960) The blood-cholesterol and blood-phospholipids are higher among Yemenites settled in Israel than among new immigrants from Yemen (Toor et al 1954, Brunner et al 1955) It was shown by one of us that there is practically no diabetes mellitus among new immigrants from Yemen, while among those settled in Israel for more than twenty-five years, its prevalence is comparable to that among Jews from the western world (Cohen 1960)

The purpose of our investigation was to determine whether the difference in environment between Yemen and Israel also affects the prevalence of involutionary sclerosis and diastolic hypertension among these contrasting groups Yemenite Jews form particularly suitable material for this study, being a homogeneous group with little or no intermarriage with other groups Constitutional factors, therefore, cannot affect the clinical differences between the settled and the new immigrant groups

In order to have the groups unselected, the entire Yemenite population above the age of 30 in chosen areas were visited in their homes The diagnosis of diastolic hypertension was based on manometric examination, and that of involutionary sclerosis on ophthalmoscopic examination of the retinal vessels This procedure seems to be as reliable as any one method for the diagnosis of involutionary sclerosis, and is probably the most suitable for a house-to-house examination It is, however, appreciated that changes in the retinal blood-vessels do not necessarily indicate changes in the entire vascular tree, nor does the absence of any change rule out the possibility of arteriosclerosis in other parts of the body

Material and Methods

The survey was carried out during 1959 The first group, the " new immigrants ", consisted of the entire population, over the age of 30, in two settlements near Jerusalem, Yishi and Noham They had all immigrated from the Yemen within the past ten years The group contained 147 persons, 70 men and 77 women The second, the " settled " group, consisted of the entire population, over the age of 30, in two Jerusalem quarters, Nahalat Ahim and Mishkenot They all had lived in Israel for over twenty-five years, and some were born there This group contained 125 persons, 55 men and 70 women All examinations were carried out at their homes Age, sex, and time of arrival to this country were noted A short physical examination was carried out in each case Resting blood-pressure was taken several times Urine was examined for albumin with sulphosalicylic acid, and for glucose with glucose reductase (' Test Tape ', Lilly)

Diastolic hypertension was considered to be present when the systolic pressure exceeded 140–150 mm Hg, and the diastolic 90 mm Hg The criteria for involutionary sclerosis were (*a*) narrow retinal arteries, (*b*) unusually straight course of these vessels, and (*c*) narrowness of their bifurcations Many of these cases showed slight variations in calibre of the arteries, and some changes at the ateriovenous crossings These were not, however, thought to be essential for the diagnosis of involutionary sclerosis The arteries were considered to

TABLE I—AGE (YEARS) AND SEX-DISTRIBUTION IN THE TWO GROUPS

—	30–55 years				Over 55 years				Total	
	M		F		M		F		M	F

* Standard deviation of the mean

be narrow and straight if at least 2 out of the main 4 vessels in each fundus were found to be affected, and the bifurcations were considered narrow if the majority of them were affected There is a certain subjective element in the diagnosis of involutionary sclerosis in the retina, and therefore only cases where there was no doubt of the retinal diagnosis were included 60% of all cases of involutionary sclerosis showed systolic hypertension Fisher's exact method for a 2×2 contingency table was used for statistical analysis

Results

Table I shows the average age in each age-group for men and women is almost the same in the " settled " and " new immigrants " groups

4 cases of diastolic hypertension (3 women and 1 man) were found among the new immigrants, and 17 (7 men, 10 women) among the settled group There was no statistical difference between men and women in each age-group of the " new " and " settled " groups in the prevalence of diastolic hypertension or involutionary sclerosis, except for ages 30–55 Except in this group, men and women were grouped together (Fisher's exact method yields relatively low probabilities even for each sex and age group separately) The prevalence of hypertension is shown in table II

TABLE II—PREVALENCE (AS A PERCENTAGE) OF DIASTOLIC HYPERTENSION IN THE TWO GROUPS

—	30–55 years	Over 55 years
New	1% (0 M, 2 F)	7% (4 M 11 F)
Settled	7 5% (7 M 8 F)	20% (20 M, 21 F)
P	0 03	0 04

Proteinuria was found once in the 4 hypertensives among the new immigrants, and five times in the 17 hypertensives among settled Yemenites

It is of interest that, though there were no diabetics among the new immigrants, there were 9 among the settled group (6 men and 3 women), 8 being more than 60 years old

The percentage of cases with involutionary sclerosis, but without diastolic hypertension or diabetes, among the new immigrants and old settlers is given in table III

TABLE III—PREVALENCE (AS A PERCENTAGE) OF RETINAL INVOLUTIONARY SCLEROSIS IN THE TWO GROUPS

—	30–55 years			Over 55 years		
	Total	M	F	Total	M	F
New	3%	0	5	8%	9	6
Settled	18 %	7	27	34%	26	33
P		0 16	0 002		0 006	

There was a statistically significant difference in the prevalence of involutionary sclerosis between the " new " and " settled " in the age-group 55+ and between " settled " and " new " women in the age-group 30–55 No significant difference was found in the men of the age-group 30–55

Discussion

It can be seen that there is a greater prevalence of diastolic hypertension, and of the ageing process as seen in the retina, among the Yemenites who have lived in Israel for over 25 years as compared with Yemenite new immigrants who have not lived for more than 10 years in the country The findings parallel the differences in the prevalence of diabetes, and in the blood-cholesterol and blood-phospholipids estimates between both groups and confirm the impression that cardiovascular disease and arteriosclerosis are more prevalent in the settled group

There is a great difference between the conditions of life in Israel and in Yemen, and there is little doubt that the different prevalences of hypertension and involutionary sclerosis between the two groups is the result of these differences The lack of intermarriage with other groups of Jews eliminates constitutional and genetic factors as an explanation of the differences The main differences between the two groups are in food habits and in the general strain of living to which they are exposed The latter can be best described as the ambition for a higher standard of living, and the general " speeding-up " involved in the Western style of culture

WE describe here a method of measuring and recording the changes in radiographic lung density during respiration We suggest that the function of a localised area of lung may be studied by correlating these density variations with simultaneous spirometric recordings

Attempts have been made by Kjellberg et al (1950) to study variations in pulmonary blood-flow by recording lung-density variations, using an electrokymographic method described by Engstrom et al (1949) Marchal et al (1946, 1949, 1959) have studied lung-density variation during respiration, paying particular attention to the pulsation of the pulmonary arteries These authors have also found that the variation in density of each lung during respiration correlates well with bronchospirometric findings Other workers (Simonin et al 1950, 1951) have attempted to study lung function by photometric comparison of the film densities on inspiration and expiration of similar areas of lung, radiographed through a kymographic grid They have compared this method with electrokymographic measurements of lung density, and compared both methods with bronchospirometry

Methods

Description of Apparatus

The apparatus is illustrated in figs 1a and b

The image of the lung field, formed on the phosphor of a 5-in Philips image-intensifier, is viewed through a binocular eyepiece to establish the exact area under examination A photomultiplier (R C A type 913) in a special mounting is substituted for the eyepiece An iris diaphragm is fitted to the

patient Fig 1 illustrates our technique, using a dialyser with 18 m of cellophane tubing

The perforated metal cylinders which form the screens for the cellophane spiral must be reinforced by a metal " skeleton " The inner cylinder would otherwise be damaged during operation by the considerable pressure resulting from application of positive pressure over a large surface Blood is pumped from the patient by a ' Sigma ' finger pump with adjustable speed (fig 1, P) The pump can be adjusted to ' occlusive " setting, which makes the rate of blood-flow relatively independent of the pressure head in A A is a simple manometer system which records the blood-pressure before it enters the proximal cellophane coils S is the cellophane spiral where ultrafiltration takes place This spiral is immersed in bath fluid B is a manometer system which records the blood-pressure as it leaves the distal coils The outflow tube can be narrowed by an adjustable screw, K, whereupon the pressure in B and in A will increase By using manometers A and B various pressure-flow relations can be recorded, this system also allows the blood flow-rate to be measured in vitro

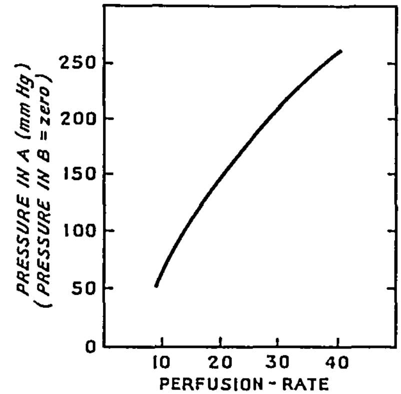

Fig 2—Pressure-flow relations in ultrafiltration with an 18 m cellophane tube, and without constriction of outflow tube

The pressure in A reaches 200 mm Hg at a perfusion-rate of 30 litres per hour

Fig 2 shows the increase in pressure in A when the rate of flow is increased without raising the pressure in B by creating a resistance at K As maximum safe pressure we have empirically chosen 200 mm Hg Above this pressure the inner cylinder may be damaged (even when reinforced) or the cellophane tube may leak 200 mm Hg pressure in A is achieved with a flow-rate of 30 litres per hour

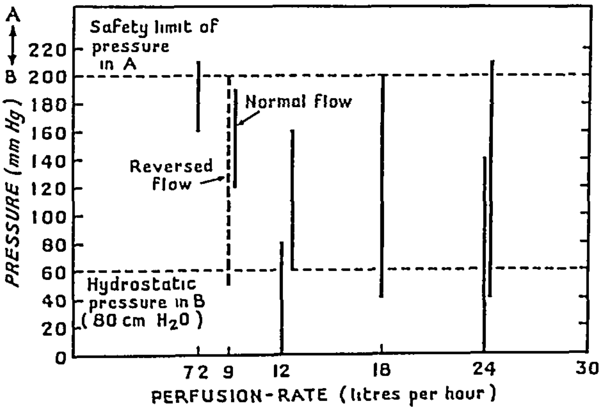

Fig 3—Pressure-flow relations with an 18 m cellophane ultrafiltrator

Pressure at B is variably increased Only moderate perfusion rates allow the pressure at B to increase considerably without excessive increase at A

Fig 3 shows the pressure-flow relations if the resistance at R is increased Each vertical column represents at the top the pressure in A, and at the bottom the pressure in B, at a certain flow-rate High flow-rates do not permit high pressures in B, because the pressure in A would then pass the safety limit Ultrafiltration will be most efficient, however, if it takes place along the whole length of the cellophane tubing, and for this a high pressure is necessary in B This can only be obtained with a moderate perfusion-rate Too low a rate is unfavourable because the blood becomes excessively dehydrated, and ultra filtration is handicapped by increasing colloid-osmotic pressure A moderate flow of 10–12 litres per hour seems to be best for ultrafiltration If the direction of blood-flow is reversed (from below upwards) the pressure difference between A and B increases considerably because the hydrostatic pressure of the bath fluid has now to be overcome at A The resulting mean pressure $\frac{(A+B)}{2}$ is lower than with a normal flow, hence the direction of the blood-stream should be downwards

The efficiency of dialysis is greater if the flow-rate is increased (fig 4) High perfusion-rates (20–30 litres per hour) result in rapid clearances and consequently short dialyses If dialysis is combined with ultrafiltration, however, moderate flows of 10–12 litres per hour seem preferable

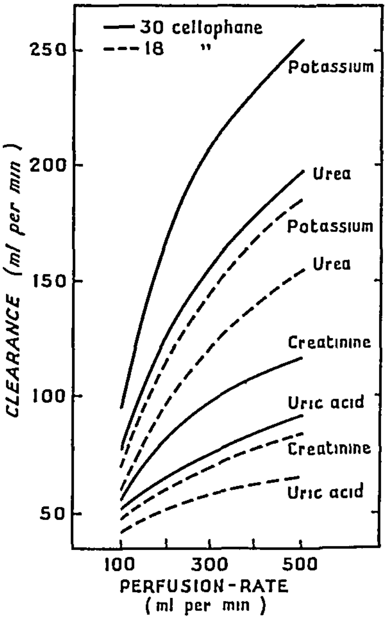

Fig 4—In-vitro clearances of the Alwall kidney at different perfusion-rates

We observed in vitro a water extraction of about 300 ml per hour—a figure which correlates well with our clinical experience and with other published data Higher rates of dehydration may lead to shock and hypotension The above rate was well tolerated by overhydrated patients, and it did not cause hypotension, although hypertension was sometimes reduced to normal

Summary

The artificial kidney of the Alwall type can be used for controlled ultrafiltration by creating a pressure difference between the extracorporeally circulating blood and the bath fluid

The optimal flow-rate for ultrafiltration is lower than that for dialysis

In clinical ultrafiltration water extraction of 300 ml per hour did not lead to hypotension if the patient was overhydrated

STAPHYLOCOCCAL PNEUMONIA IN THE NEONATAL PERIOD

THE pattern of tissue reaction to microbial infection varies with the virulence of the organism, the resistance of the host, and occasionally with the portal by which the organism gains access Neonatal lung infection with the staphylococcus illustrates this point

We describe here eight examples of staphylococcal pneumonia in the neonate which occurred during the period March, 1958, to August, 1959 They illustrate the often fulminant character of the infection and the variety of histological appearances in the lungs, and emphasise the need for the diligent use of the aseptic method in the care of the newly born

Illustrative Case-record

Stillborn infant, aged 39 weeks The mother, a multipara aged 31, was admitted with toxæmia on Aug 5, 1959, at 37th week of pregnancy She was kept in bed, but her hypertension did not lessen and it was decided to induce labour by hind-water rupture of the membranes, this was done on Aug 14 The next day an oxytocin (' Pitocin ') drip was given which induced uterine contractions

The temperature rose to 105°F on the following day, with a rigor, tenderness was noted in the right loin and right iliac fossa A diagnosis of pyelitis of pregnancy was made, urine examination showed a few pus cells, and *Proteus vulgaris* was cultured A high vaginal swab produced a growth of *Staphylococcus pyogenes*, sensitive to most antibiotics, the organism was not present in the patient's nose Benzyl penicillin (penicillin G) 500,000 units and streptomycin 0 5 g were given twice daily On the same day, when the cervix was two finger breadths dilated, at approximately 1 30 P M , the fœtal heart sounds became inaudible

She was delivered at 3 45 P M on Aug 16 of a stillborn male fœtus weighing 5¹/₄ lb (2410 g) Her temperature became normal next day, and recovery was uneventful

Necropsy

Tiny hæmorrhages were scattered over the visceral pleuræ of both lungs and over the visceral pericardium Small quantities of blood-stained fluid were seen in both pleural and pericardial cavities The spleen weighed 14 g , and appeared normal

No other abnormality was found The placenta and umbilical cord appeared normal macroscopically

Histological Findings

Lungs —All lobes of the lungs contained areas of intra-alveolar hæmorrhage, mingled with clusters of polymorphonuclear leucocytes and clumps of staphylococci There were numerous epithelial squames in alveoli and alveolar ducts A few veins contained thrombi

Placenta —Areas of purulent infiltration were seen in sections of placenta and umbilical cord

Bacteriological Investigations

The lungs and spleen were examined by the method described by Gresham and Gleeson-White (1957) All lobes grew a strain of *Staph pyogenes*, sensitive to all antibiotics against which it was tested (case 8, table III) The spleen was sterile

The findings in the other cases in this series are summarised in table I

Discussion

All infants showed histological evidence of pneumonia which varied from predominantly hæmorrhagic to frankly purulent infiltration In every case *Staph pyogenes* was isolated from the lungs

The histological appearances in the lungs could be classified broadly into three main groups

1 Extensive intra-alveolar hæmorrhage with necrosis of alveolar walls, together with abundant staphylococci Polymorphonuclear leucocytic infiltration was scanty This appears to represent an overwhelming infection—the organism being at the peak of its virulence and the host resistance low Two cases (1 and 6) fall into this group

2 Five showed the usual appearances of bacterial bronchopneumonia with sparse intrapulmonary hæmorrhage The duration of illness in these cases (3–7) was of the order of days rather than hours, as in the first group

3 One showed sparse polymorphonuclear leucocytic infiltration in alveoli (case 2) The staphylococcus was isolated both from the lung and from the spleen The changes in the lungs reflected those seen in other organs and were due to septicæmia

Five cases were infected with *Staph pyogenes* of the same antibiotic resistance patterns as those of the indigenous hospital staphylococcus This suggested that the source of infection was the hospital environment The route of infection in at least four of these was probably vaginal, three showed placentitis on histological examination In one (case 7) the infant was delivered at another hospital and the placenta was not available Nevertheless, the mother's vagina contained a *Staph pyogenes* similar in antibiotic resistance pattern to that isolated from the fœtal lung The finding of placentitis strongly supports the view that the bronchopneumonia in the fœtus was due to inhalation of infected amniotic fluid Further evidence

Analysis of the density curves is concerned with (1) the amplitude of the density variation in relation to the spirometer tracings, and (2) alterations in the time relationship between the two tracings

To illustrate these points two examples are described

Case 1 *Pulmonary emphysema with bullous emphysema of the right lower zone*—The spirometer tracings were similar during the examination of each of the four areas Normal respiration with a tidal flow of 1000–1200 ml of air was followed by a full inspiration (held for approximately 5 sec) and finally the forced expiration of approximately 2000 ml of air The forced expiration was considerably slower than in the normal subject (fig 6)

In the areas examined, the density tracings show considerable differences in amplitude and timing The left lower-zone tracing appears almost normal, following the spirometer curve closely The curve is synchronous with the spirometer tracing and the only abnormality is that, on forced expiration, the rate of loss of density is less than in the normal In the left upper-zone tracings, on forced expiration, there is a rapid initial loss of density, followed by a sudden check, and then a more gradual loss of density This contrasts with the smooth curve obtained from the lower zone The density tracing in the right upper zone is similar on forced expiration, but there is very little variation in lung density on normal respiration The density tracing in the right lower zone is grossly abnormal The density and spirometer curves are completely out of phase During respiration, the lung becomes more dense on inspiration and less dense on expiration On forced expiration, the lung initially becomes a little less dense and then shows no further change, even though the spirometer curve indicates that air is being expired from the lungs as a whole

Comment—The left lower zone is the area in which the tracings are nearest to normal There is the good synchronous variation in density with respiration, and an even loss of density on forced expiration This suggests that the most useful air movement is taking place in this area of the lung The upper zones, by comparison, show little variation in density on respiration On forced expiration, the sudden check in the density curve suggests that there is partial air-trapping after the start of expiration

The curves in the right lower zone are paradoxical, the density curve shows brightening on expiration The explanation for this is not known, but it may be due to air movement within the lungs, the air flowing into this region from other parts of the lungs

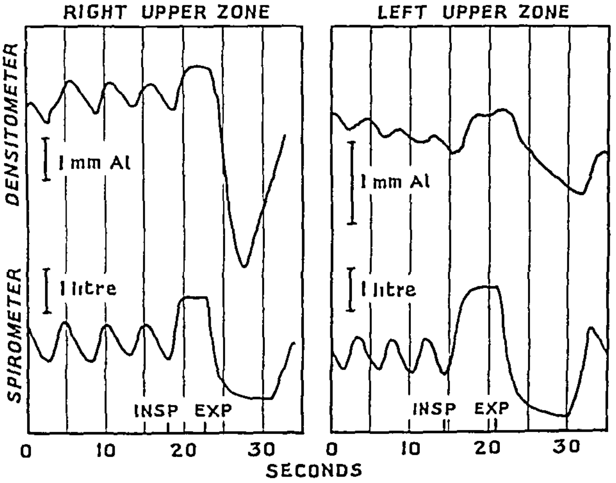

Fig 7—Case 2 Unilateral hypertranslucency of the left lung

The most important features are the smaller amplitude of density change on respiration and the slower rate of loss of density on forced expiration of the left upper zone compared with the right Since the densitometer sensitivity was greater when the left recording was made, the difference between the two sides is greater than appears at first sight

Case 2 *Radiological translucency of one lung*—A young man, without symptoms, was found, on routine X-ray examination, to have unilateral hypertranslucency of the left lung (Macleod 1954) The right pulmonary arteries appeared normal but the left pulmonary arteries appeared abnormally small Fluoroscopic examination showed that on expiration the left lung failed to deflate fully and the mediastinum swung to the right

The tracings obtained for the right and left upper zones are shown in fig 7 The spirometer tracings were similar when the two areas were examined The density and spirometer curves show synchronous movement But on normal respiration there is a much smaller amplitude of density change in the left upper zone when compared with the right On forced expiration, there is a much slower rate of loss of density in the left than in the right lung Similar changes were found in other zones It should be noted that the densitometer sensitivity was greater when recording the left side than when recording the right side (see scale fig 7), which means that the actual difference in density is greater than appears on the graphs

Comment—The small variation in lung density on normal respiration and the slow loss of density on forced expiration probably indicate that there is a much reduced air flow into and out of the left lung when compared with the right

Discussion

A number of factors, pulmonary and extrapulmonary, influence the overall radiolucency of the lung-fields during respiration The extrapulmonary factors are the ribs and soft tissues of the thoracic cage Their influence on the density curves is small On inspiration, the girth of the thoracic cage increases, thinning the overlying soft tissues and making them slightly more radiolucent This change is in phase with and slightly augments the overall pulmonary density curve The change in density caused by the ribs moving across the field during respiration is less regular than the soft-tissue effect By choosing a 5 cm diameter field, it is possible to even out the density changes produced by the ribs For example, the effect of the ribs and soft tissues over a pneumothorax, when no lung is in the field, is small compared with the changes in density over a normal lung field

The variation in radiolucency attributable to the pulmonary components are due to changes in blood contents and changes in air contents, the vascular component causes only a small ripple on the relatively large pulmonary density curve The main density changes are due to the air component

Sokolov (1956) has shown, by inflating the lungs of cadavers under experimental conditions, that the decrease in density which occurs with pulmonary inflation is dependent upon the total amount of lung tissue through which the X rays pass, and that this depends mainly on the amount of lung expansion which takes place in directions perpendicular to the rays Thus, in an anterior view of a lung, the decrease in density is influenced mainly by expansion in the vertical and transverse directions, in the coronal plane, and only little by expansion in the anteroposterior direction

The alterations of lung density during respiration, recorded by our densitometer, are a function of the degree of expansion of the part of lung under observation, and hence of the amount of air exchanged Since the observations are carried out under dynamic conditions, the curves give some indication of the air flow into and out of this part of the lung There is a recognisable normal pattern of tracings in different parts of the lung fields When there are abnormalities, correlation of the density tracings in the different areas with the spirometer tracings allows one to detect abnormalities of air flow When alterations in lung density occur without spirometer movement, intrapulmonary air flow must be taking place When there is localised air trapping, the densitometer tracing may show a slow rate of loss of density even though the spirometer tracings may be relatively normal Normally the densitometer and spirometer tracings are synchronous Asynchronous curves imply localised air-flow obstruction, or even reversal, as in one of our cases

The place of this radiological technique in the study of lung function has not yet been fully assessed It is hoped to correlate this method with other more conventional lung-function tests in order to establish its clinical value as a routine procedure

Summary

A radiological method of studying localised changes in lung density during respiration is described Simultaneous spirometer recordings are made

The curves obtained in normal and abnormal patients are described and analysed

The significance and interpretation of these findings is discussed

We wish to thank Mr C R. Brecknell for the figures, and Dr G C. Rivett for allowing us to carry out density studies on case 2

OPTIMAL PERFUSION-RATE IN HÆMODIALYSIS COMBINED WITH ULTRAFILTRATION

E E Twiss
M.D Amsterdam

M M P Paulssen
Ph D Amsterdam

DIALYSIS DEPARTMENT, ST CLARA HOSPITAL, ROTTERDAM, THE NETHERLANDS

In acute renal insufficiency patients not infrequently become overhydrated as water is liberated from the cells by catabolic processes Water is also formed by oxidation of body fat and dextrose To prevent overhydration the intake of water must be rigorously restricted (to 400–500 ml per day) during the anuric phase Overhydration may lead to pulmonary œdema and bronchopulmonary infection, and cerebral œdema sometimes causes convulsions, especially when too much sodium has been given in an attempt to correct acidosis

If progressive uræmia is complicated by severe overhydration, treatment with combined hæmodialysis and ultrafiltration is indicated Ultrafiltration occurs if the pressure in the extracorporeally circulating blood (i e, the colloid-osmotic pressure of the plasma) is at least 30 mm Hg higher than the pressure in the surrounding bath fluid, this is technically feasible only if the filter membrane (' Cellophane ') is supported by a rigid screen which prevents changes of the extracorporeal blood-volume Kolff's rotating kidney lacks this support, and therefore cannot be used as an ultrafiltrator Kolff's twin-coil kidney, however, is supported, in this type of kidney ultrafiltration is obligatory because the high inner resistance of the narrow cellophane coils demands a high perfusion pressure But the Skegg-Leonards and Alwall types of kidney seem preferable because they both give support to the cellophane membrane and allow controlled ultrafiltration

Method

In our department a modified Alwall dialyser has been used since 1952 Under standard conditions the patient loses no water As the inner resistance of the cellophane tubing spiral is low, a moderate perfusion pressure suffices for satisfactory flow This slight " over " pressure is partially compensated by the colloid-osmotic pressure and partially by the hydrostatic pressure of the bath fluid If the direction of flow through the cellophane spiral is from above downwards, the proximal coils will cause some ultrafiltration because the blood-pressure is high and the hydrostatic pressure of the bath fluid is low The distal coils will take up water from the bath because the perfusion pressure is low and the hydrostatic pressure of the bath is high In practice this maintains the water balance, as is shown by weighing the patient with a bed scale before, during, and after dialysis The bath fluid we use is not hypertonic to uræmic plasma

Ultrafiltration is made possible by placing an airtight lid on the bath-fluid reservoir, so creating a negative pressure in the air above the bath fluid The hydrostatic pressure in the bath will thus be lowered, and a pressure gradient will be established between bath fluid and blood This method has several disadvantages, including the high cost of airtight apparatus, the maintenance of a constant vacuum, and the sudden changes in blood-volume which arise during the rapid creation of a vacuum (although these changes are limited by the screen support, they may disturb the patient) A much simpler, cheaper, and easier way is to raise the pressure of the circulating blood This can be done by using a higher perfusion-rate, and by increasing the resistance in the circuit by constricting the outflow tube from the " kidney " to the

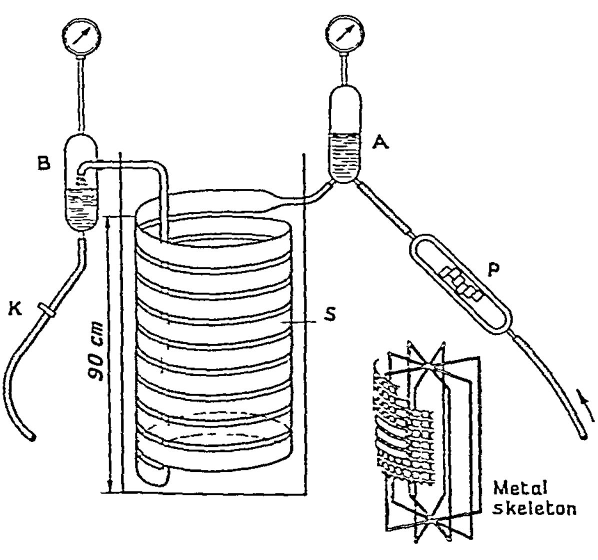

Fig 1—Schematic drawing of the Alwall kidney as ultrafiltrator P=finger pump A and B=manometers respectively proximal and distal to the cellophane spiral, S K=adjustable screw

patient Fig 1 illustrates our technique, using a dialyser with 18 m of cellophane tubing

The perforated metal cylinders which form the screens for the cellophane spiral must be reinforced by a metal " skeleton " The inner cylinder would otherwise be damaged during operation by the considerable pressure resulting from application of positive pressure over a large surface Blood is pumped from the patient by a ' Sigma ' finger pump with adjustable speed (fig 1, P) The pump can be adjusted to ' occlusive " setting, which makes the rate of blood-flow relatively independent of the pressure head in A A is a simple manometer system which records the blood-pressure before it enters the proximal cellophane coils S is the cellophane spiral where ultrafiltration takes place This spiral is immersed in bath fluid B is a manometer system which records the blood-pressure as it leaves the distal coils The outflow tube can be narrowed by an adjustable screw, K, whereupon the pressure in B and in A will increase By using manometers A and B various pressure-flow relations can be recorded, this system also allows the blood flow-rate to be measured in vitro

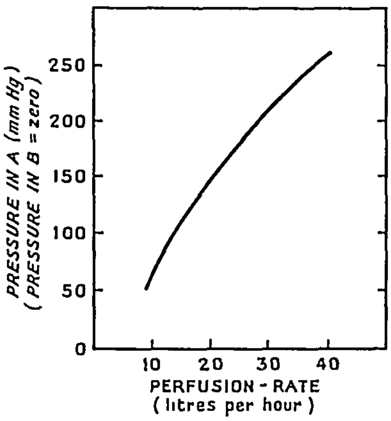

Fig 2—Pressure-flow relations in ultrafiltration with an 18 m cellophane tube, and without constriction of outflow tube

The pressure in A reaches 200 mm Hg at a perfusion-rate of 30 litres per hour

Fig 2 shows the increase in pressure in A when the rate of flow is increased without raising the pressure in B by creating a resistance at K As maximum safe pressure we have empirically chosen 200 mm Hg Above this pressure the inner cylinder may be damaged (even when reinforced) or the cellophane tube may leak 200 mm Hg pressure in A is achieved with a flow-rate of 30 litres per hour

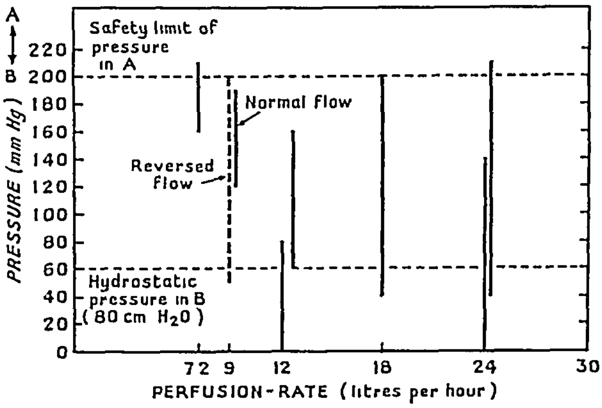

Fig 3—Pressure-flow relations with an 18 m cellophane ultrafiltrator

Pressure at B is variably increased Only moderate perfusion rates allow the pressure at B to increase considerably without excessive increase at A

Fig 3 shows the pressure-flow relations if the resistance at R is increased Each vertical column represents at the top the pressure in A, and at the bottom the pressure in B, at a certain flow-rate High flow-rates do not permit high pressures in B, because the pressure in A would then pass the safety limit Ultrafiltration will be most efficient, however, if it takes place along the whole length of the cellophane tubing, and for this a high pressure is necessary in B This can only be obtained with a moderate perfusion-rate Too low a rate is unfavourable because the blood becomes excessively dehydrated, and ultrafiltration is handicapped by increasing colloid-osmotic pressure A moderate flow of 10–12 litres per hour seems to be best for ultrafiltration If the direction of blood-flow is reversed (from below upwards) the pressure difference between A and B increases considerably because the hydrostatic pressure of the bath fluid has now to be overcome at A The resulting mean pressure $\frac{(A+B)}{2}$ is lower than with a normal flow, hence the direction of the blood-stream should be downwards

The efficiency of dialysis is greater if the flow-rate is increased (fig 4) High perfusion-rates (20–30 litres per hour) result in rapid clearances and consequently short dialyses If dialysis is combined with ultrafiltration, however, moderate flows of 10–12 litres per hour seem preferable

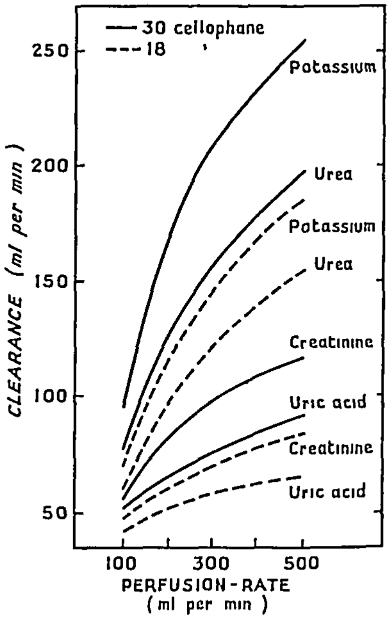

Fig 4—In-vitro clearances of the Alwall kidney at different perfusion-rates

We observed in vitro a water extraction of about 300 ml per hour—a figure which correlates well with our clinical experience and with other published data Higher rates of dehydration may lead to shock and hypotension The above rate was well tolerated by overhydrated patients, and it did not cause hypotension, although hypertension was sometimes reduced to normal

Summary

The artificial kidney of the Alwall type can be used for controlled ultrafiltration by creating a pressure difference between the extracorporeally circulating blood and the bath fluid

The optimal flow-rate for ultrafiltration is lower than that for dialysis

In clinical ultrafiltration water extraction of 300 ml per hour did not lead to hypotension if the patient was overhydrated

STAPHYLOCOCCAL PNEUMONIA IN THE NEONATAL PERIOD

THE DEPARTMENT OF PATHOLOGY, UNIVERSITY OF CAMBRIDGE

THE pattern of tissue reaction to microbial infection varies with the virulence of the organism, the resistance of the host, and occasionally with the portal by which the organism gains access Neonatal lung infection with the staphylococcus illustrates this point.

We describe here eight examples of staphylococcal pneumonia in the neonate which occurred during the period March, 1958, to August, 1959 They illustrate the often fulminant character of the infection and the variety of histological appearances in the lungs, and emphasise the need for the diligent use of the aseptic method in the care of the newly born.

Illustrative Case-record

Stillborn infant, aged 39 weeks The mother, a multipara aged 31, was admitted with toxæmia on Aug 5, 1959, at 37th week of pregnancy She was kept in bed, but her hypertension did not lessen and it was decided to induce labour by hind-water rupture of the membranes, this was done on Aug 14. The next day an oxytocin ('Pitocin') drip was given which induced uterine contractions

The temperature rose to 105°F on the following day, with a rigor, tenderness was noted in the right loin and right iliac fossa. A diagnosis of pyelitis of pregnancy was made, urine examination showed a few pus cells, and *Proteus vulgaris* was cultured A high vaginal swab produced a growth of *Staphylococcus pyogenes*, sensitive to most antibiotics, the organism was not present in the patient's nose Benzyl penicillin (penicillin G) 500,000 units and streptomycin 0 5 g were given twice daily On the same day, when the cervix was two finger breadths dilated, at approximately 1.30 P.M., the fœtal heart sounds became inaudible.

She was delivered at 3 45 P M. on Aug 16 of a stillborn male fœtus weighing 5¹/₄ lb (2410 g) Her temperature became normal next day, and recovery was uneventful.

Necropsy

Tiny hæmorrhages were scattered over the visceral pleuræ of both lungs and over the visceral pericardium. Small quantities of blood-stained fluid were seen in both pleural and pericardial cavities The spleen weighed 14 g, and appeared normal.

No other abnormality was found. The placenta and umbilical cord appeared normal macroscopically

Histological Findings

Lungs.—All lobes of the lungs contained areas of intra-alveolar hæmorrhage, mingled with clusters of polymorphonuclear leucocytes and clumps of staphylococci. There were numerous epithelial squames in alveoli and alveolar ducts A few veins contained thrombi.

Placenta.—Areas of purulent infiltration were seen in sections of placenta and umbilical cord.

Bacteriological Investigations

The lungs and spleen were examined by the method described by Gresham and Gleeson-White (1957) All lobes grew a strain of *Staph pyogenes*, sensitive to all antibiotics against which it was tested (case 8, table III) The spleen was sterile

The findings in the other cases in this series are summarised in table I

Discussion

All infants showed histological evidence of pneumonia which varied from predominantly hæmorrhagic to frankly purulent infiltration. In every case *Staph pyogenes* was isolated from the lungs

The histological appearances in the lungs could be classified broadly into three main groups

1 Extensive intra-alveolar hæmorrhage with necrosis of alveolar walls, together with abundant staphylococci Polymorphonuclear leucocytic infiltration was scanty This appears to represent an overwhelming infection—the organism being at the peak of its virulence and the host resistance low Two cases (1 and 6) fall into this group

2 Five showed the usual appearances of bacterial bronchopneumonia with sparse intrapulmonary hæmorrhage The duration of illness in these cases (3–7) was of the order of days rather than hours, as in the first group

3 One showed sparse polymorphonuclear leucocytic infiltration in alveoli (case 2) The staphylococcus was isolated both from the lung and from the spleen. The changes in the lungs reflected those seen in other organs and were due to septicæmia

Five cases were infected with *Staph pyogenes* of the same antibiotic resistance patterns as those of the indigenous hospital staphylococcus This suggested that the source of infection was the hospital environment. The route of infection in at least four of these was probably vaginal, three showed placentitis on histological examination In one (case 7) the infant was delivered at another hospital and the placenta was not available Nevertheless, the mother's vagina contained a *Staph pyogenes* similar in antibiotic resistance pattern to that isolated from the fœtal lung The finding of placentitis strongly supports the view that the bronchopneumonia in the fœtus was due to inhalation of infected amniotic fluid. Further evidence

TABLE I—CLINICAL FEATURES

Case no	Antenatal history	Duration of pregnancy in weeks	Delivery	Stillbirth or neonatal death	History of infant	Duration of life
1	Essential hypertension toxæmia. P.R.M.	31	Normal	N.N.D	Neonatal asphyxia intragastric oxygen	42 hours

S=sensitive R=resistant

for the view that inhalation was the route of pneumonic infection is provided by the occurrence of fœtal distress, and the presence of numerous amniotic squames in the air-passages of all infants in which this route is postulated A vaginal route of infection is also supported by the fact that an undue number of vaginal procedures were made in the antenatal period, these were carried out because of a high incidence of antenatal complications in these mothers (table I)

The sensitivity of the organisms to various antibiotics is shown in table III Three strains were sensitive to all the antibiotics against which they were tested These three organisms were probably derived from the mothers themselves, or from a newly introduced strain carried into the ward Case 8 (table I) is typical, a high vaginal swab from the mother before delivery showed a sensitive strain of *Staph pyogenes*

In three cases the mother's vagina did not grow *Staph pyogenes* though it was isolated from the fœtal lungs However, the interval of several days between delivery and taking a vaginal swab may explain this discrepancy

Cases 4 and 5 (table I) were infants with congenital abnormalities They survived much longer than all other infants in this series The organism responsible for their pneumonia had the same resistance pattern as the indigenous hospital staphylococcus They were probably infected post partum There were no inflammatory changes of the umbilical cord or placenta in case 4 The other placenta was not available

Three cases showed œsophagitis, associated with intubation and the administration of gastric oxygen The lesion was probably incidental, and was not the primary source of infection

All infants were premature as judged by weight The number of ossification centres found at necropsy varied from case to case (table III) Most were found in case 5—an infant with multiple congenital abnormalities This suggests that such babies may be expected to develop lung infections, either because prematurity reflects antenatal complications and the need for excessive manipulations, or because they are unduly susceptible to infection

Summary

Eight cases of fatal staphylococcal pneumonia in neonates are described The infection was often fulminant, and a variety of histological appearances—ranging from extensive intra-alveolar hæmorrhage with necrosis of the alveolar walls to a slight polymorphonuclear leucocytic infiltration—were found post mortem

The causal organism in every case was *Staphylococcus pyogenes* It is suggested that in six of the infants the bronchopneumonia was due to the inhalation of infected amniotic fluid, two cases were probably infected post partum The need for diligent application of aseptic methods in the care of the newly born is stressed

Our thanks are due to Dr A M Barrett, Dr D M T Gairdner, and Dr M H Gleeson-White for their cooperation in the preparation of this paper

GONADAL DYSGENESIS (TURNER'S SYNDROME) WITH MALE PHENOTYPE AND XO CHROMOSOMAL CONSTITUTION

WALTER BLOISE
M.D. São Paulo

L. M. DE ASSIS
M.D. São Paulo

CASSIO BOTTURA
M.D. Ribeirão Preto

IRIS FERRARI
M.D. Ribeirão Preto

From the Department of Endocrinology and Metabolic Disorders, Faculty of Medicine, São Paulo, and the Department of Clinical Medicine, Faculty of Medicine, Ribeirão Preto, Brazil

A boy, aged 8, the eldest son of young parents, was admitted to the metabolic department on April 5, 1957, because of poor somatic development.

Maternal pregnancy and labour had been normal. General condition was fair. Height 3 ft. 9 in. (115 cm.), weight 45·4 lb. (20·6 kg.), span 3 ft. 7 in. (110 cm.) (fig. 1). Clinical examination revealed malformed external genitalia and some lesser congenital defects—low hair-line and ears, high-arched palate, and a number of naevi. The penis 1·2 in. (3·1 cm.) long, without urethral meatus, was bent ventrally by a web connecting the ventral surface to the perineum. Thus the "scrotum" appeared to be bifid, a depression with two small meatuses being visible in the midline, one communicated with the bladder through a short urethra, and the other led to a closed cavity (fig. 2). When the patient underwent plastic surgery, it was verified this cavity communicated with the uterus. No testes could be felt in the labioscrotal folds or in the inguinal regions. A rudimentary uterus was seen on peritoneoscopy and a laparotomy was done for further investigation of the internal genitalia. Near the small left tube was an elongated, almond-shaped mass $^3/_8$ in. (1 cm.) long, which was histologically a rudimentary testis (figs. 3 and 4). On the right, instead of an ovary, there was connective tissue, as seen in other cases of gonadal dysgenesis with negative chromatin pattern (Epps et al. 1958). 17-ketosteroids (Drekter) 0·8 mg. per 24 hours. Bone age of 7 years, X-ray examination of the skull, no abnormality. Colour-vision normal (Ishihara tests).

The nuclear sex in material obtained from the blood, oral smear, and from the skin biopsy was male. In the blood-smears, no "drumsticks" were found in 500 leucocytes counted. Chromosomal counts (Bottura and Ferrari 1960) in the 20 bone-marrow specimens examined gave a constant number of 45 chromosomes. In the 13 cells in optimal condition, 4 small acrocentric chromosomes could be positively identified. After pairing (fig. 5), the absence of a second medium-sized chromosome with subcentral centromere (probably an X chromosome) was noted. In view of these facts, the chromosomal constitution of the patient must be XO. The constancy of the number 45 in the chromosomal counts argues against

the possibility of mosaicism as far as bone-marrow cells are concerned

Discussion

XO chromosomal constitution in gonadal dysgenesis with female phenotype was described by Ford et al (1959) A reasonable assumption from the study of our case is that XO chromosomal constitution is not incompatible with a male phenotype and with the presence of embryonic testis Further instances of testicular development with a male phenotype without Y chromosome are represented by the XX true hermaphrodites recently reported (Harnden and Armstrong 1959, Hungerford et al 1959, de Assis et al 1960, Ferguson-Smith et al 1960)

Summary

We describe a case of gonadal dysgenesis (Turner's syndrome) in a boy of 8 He had a rudimentary uterus, and an embryonic testis No ovaries were found The nuclear sex was male " Drumsticks " were absent from the leucocytes Only 45 chromosomes were present in the cells of all (20) bone-marrow specimens examined, and chromosome analysis pointed to the absence of one X chromosome His phenotype is, therefore, male with an XO chromosomal constitution

M D Cantab , M R C P , D C H
ASSISTANT TO THE DIRECTOR OF THE DEPARTMENT OF CHILD HEALTH

R J Vale
M B Lond , M R C P E , F F A R C S
CONSULTANT ANÆSTHETIST

GUY'S HOSPITAL, LONDON, S E 1

In 1872 Heidenhain demonstrated that the salivary secretion produced by stimulation of the chorda tympani was prevented by atropine, and, in the next year, Ebstein used it therapeutically in a patient with apoplexy In 1875 Munro reported its use in cats for preventing early cardiac arrest during chloroform anæsthesia, but it was not until after 1890 that the subcutaneous injection of atropine before induction of anæsthesia came into general use in this country

There seems to be no record of the oral administration of atropine before operation, though it is used therapeutically for various conditions Even when sedative drugs are given by mouth preoperatively, it has still been common practice to inject atropine, though Dr W S McConnell tells us he has used it by mouth effectively In children it is especially desirable to avoid injections, hence we conducted this trial of the effect of atropine given by mouth

The Trial

All children admitted to the Evelina Hospital, under the same surgeon and anæsthetist for tonsillectomy, were included in the trial When admitted, the day before the operation, the child was placed in an " oral " or " subcutaneous " group by random allocation, the anæsthetist being unaware of the grouping The trial lasted fifteen months, and ended when the anæsthetist ceased to work at this hospital

240 children were admitted to the trial, but 93 were excluded because a different anæsthetist was working on that occasion or because the data were incomplete There remained 147 children for study Their sex, average weights, and ages were

	No	*Males*	*Females*	*Age (yr)*	*Weight (lb)*
Oral	74	41	33	6 5	49
Subcutaneous	73	39	34	6 7	51

and the age-distribution was

	No	*3–5 yr*	*6–8 yr*	*9–12 yr*
Oral	74	21	44	9
Subcutaneous	73	17	15	11

The average interval between administration of atropine and induction of anæsthesia was 95 and 87 minutes for the oral and subcutaneous groups respectively

During the night before operation the sleeping pulse was measured twice Next morning, an hour before the expected time of operation, atropine was given—either 0 85 mg by mouth or 0 64 mg subcutaneously—with butobarbitone, in a dose of 75 mg per stone body-weight The pulse-rate was recorded again just before the child was taken to the operating-theatre, and the state of consciousness was noted In the anæsthetic-room the size of the pupils was measured to the nearest millimetre by comparison with a prepared scale, and the reaction to light was noted All patients were anæsthetised with ether after induction with either ethyl chloride on a Schimmelbusch mask or nitrous oxide and oxygen through a semiopen circuit The degree of salivation was assessed during induction by inserting a finger into the buccal sulcus, if it was dry or slightly moist, it was recorded as O, if wet but not dripping off the finger as +, and if copious and stringy as ++ Additionally, if salivation interfered with induction, it was recorded as ++

Results

Salivation

The degree of salivation was

	No	*O*	+	++
Oral	74	63	9	2
Subcutaneous	73	68	4	1

Excessive salivation was uncommon in either group, occurring only twice in the oral group and once in the subcutaneous group There was a little more mild salivation in the oral group than in the subcutaneous group, but the difference was small and not significant at the 5% level

Pupils

The average size of the pupils was identical in the two groups, and the incidence of negative reaction to light was similar

	No	*Size (mm)*	*Negative reaction*
Oral	74	6 1	15 (*19%*)
Subcutaneous	73	6 1	11 (*15%*)

Pulse-rate

The response of the pulse-rate was

	No	*Before atropine*	*After atropine*	*Rise*
Oral	74	85	107	22
Subcutaneous	73	86	111	25

The mean rate before atropine was similar in both groups, there being a rise of 22 and 25 beats per minute in the oral and subcutaneous groups respectively

Discussion

Dose

Unna et al (1950) have shown that the smallest effective dose of atropine for suppression of salivation in children aged 3–12 years is about 0 007 mg per kg body-weight subcutaneously, or three times this dose by mouth The dose for a 20 kg child is about a quarter the dose of

0 64 mg commonly used subcutaneously Mushin and Galloon (1953) also regard 0 64 mg subcutaneously as more than is needed to suppress salivation Thus our subcutaneous dose was probably three times larger than necessary, and our oral dose was the smallest effective dose recommended by Unna et al

Salivation

Although we evaluated the effect of atropine by several criteria, the suppression of salivation is especially important in premedication, and is also the most sensitive index of the effect of atropine (Unna et al 1950) Our finding of excessive salivation in 2% was similar to the 4% observed by Marx and Orkin (1959), but their figures were for atropine and scopolamine, and they pointed out that their atropine group had more secretion than their scopolamine group

During our study atropine was deliberately not given to a few patients, in order to establish that it had some effect But the excessive salivation and extreme bradycardia in the first five children so treated made us unwilling to continue, and we resumed the trial Mushin and Galloon (1953) pointed out that the degree of salivary depression necessary depended on the type of anæsthesia used, ether needing about 40% and nitrous oxide about 10% depression We used ether, and therefore our patients needed maximum depression of salivation

Pupils and Pulse-rate

Both mydriasis and tachycardia are unreliable signs of the effect of atropine, because anxiety, excitement, or barbiturates may also produce these signs, but atropine was probably responsible for mydriasis in some of our patients, as the correlation between size of pupil and reaction to light was significant

	No	*Size of pupil (mm) with positive reaction*	*No*	*Size of pupil (mm) with negative reaction*
Oral	59	5 7 ± 0 19	15	7 8 ± 0 82
Subcutaneous	62	5 8 ± 0 19	11	8 1 ± 0 96

Difference in size of pupils is significant ($P = < 0\ 05 > 0\ 02$)

We cannot be sure that the rise of pulse-rate was solely due to atropine, although it probably made a substantial contribution. The rise in pulse-rate was similar in both our groups

We were unable to show any correlation between pupil size, rise in pulse-rate, and salivation However, we found correlation between the size of pupil and its response to light, the fixed pupils having a mean diameter of 7 8 and 8 1 mm (oral and subcutaneous) compared with 5 7 and 5 8 mm for the active pupils It is interesting that we found this correlation in the oral group, for Unna et al (1950) pointed out that the smallest dose by mouth which suppressed salivation did not cause mydriasis or tachycardia

The average time between giving atropine and inducing anæsthesia was 95 and 87 minutes in the two groups This interval is similar to that observed by Unna et al (1950), who found the greatest effect of atropine was between sixty and a hundred and twenty minutes for an oral group, and to that of Mushin and Galloon (1953), who found the greatest effect between sixty and ninety minutes for a subcutaneous group

Our investigation has shown that, in children, atropine given by mouth is as effective as atropine given by subcutaneous injection As it is desirable to avoid injection in children, the oral route seems preferable

Summary

147 children randomly selected were given oral or subcutaneous atropine before anæsthesia, and the effects on salivation, pupils, pulse-rate, and anæsthesia were observed No differences between the groups were found

Thus is it concluded that atropine by mouth is satisfactory for premedication

We wish to thank the nursing staff and residents at the Evelina *Children's Hospital for their help, and Mr L F W Salmon for* allowing us to conduct this trial on patients under his care

Preliminary Communications

ANTINUCLEAR FACTORS IN THE SERUM OF RELATIVES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

DURING an investigation of antinuclear factors in the serum of patients with systemic lupus erythematosus (S L E) we found a relationship between the titre of antinuclear factors in the serum and the clinical activity of the disease High titres were found in patients with active S L E , the titres were considerably lower in most patients in whom the disease was adequately controlled by treatment with prednisone[1] As this test for antinuclear factors was sensitive, and as the results could be quantitated, we were prompted to examine the serum of relatives of patients with S L E for antinuclear factors, particularly in view of recent reports of the familial occurrence of S L E [2–8]

MATERIAL AND METHODS

Smears of fresh unfixed healthy human buccal mucosal epithelial cells were used as the source of the cell nuclei After washing with 0 01 *M* saline phosphate buffer (pH 7 0) the slides were air-dried, and the smears were covered with a drop of the test serum The smears were incubated for 90 minutes at room temperature in a moist atmosphere The slides were washed for 30 minutes in three changes of buffer, air-dried, and layered for 30 minutes with rabbit antihuman γ-globulin conjugated with fluorescein isothiocyanate (Sylvana) They were washed and were then mounted in buffered glycerin They were inspected for specific nuclear fluorescence, using a Reichert Zetopan microscope with an aplanatic dark field condensor (light source Osram HBO 200 mercury-vapour lamp, Corning 5840 and Wratten 2A filters)

All tests were done in duplicate When specific nuclear fluorescence was found, serial dilutions of serum (to 1 4096) were incubated with smears of buccal mucosal cells in a similar fashion The highest dilution in which specific nuclear fluorescence was detected was called the ' titre " of antinuclear factors

Full details of the technique and controls used will be published elsewhere[1] It was shown that duplicate titrations on the same sera gave identical titres in 4 of 10 instances The final titres differed by only one dilution in the other 6

RESULTS

The results are shown in table I Single serum samples from 40 healthy subjects and 50 sera from 45 patients with

TABLE I—TITRES OF ANTINUCLEAR FACTORS IN HEALTHY SUBJECTS, IN PATIENTS WITH VARIOUS DISEASES UNRELATED TO S L E , AND IN PATIENTS WITH S L E AND THEIR RELATIVES

Titre of Antinuclear factors (dilution)	Healthy subjects	Diseases unrelated to S L E	Patients with S L E	Relatives of patients with S L E
Negative				
Undiluted	33	40	3	20
1:1	3	5	2	3
1:2	4	4	1	3
Positive				
1:4 to 1:16	0	1	12	17
1:32 to 1:128	0	0	14	4
1:256 to 1:4096	0	0	19	3

diseases unrelated to S L E were studied as controls Specific nuclear fluorescence was not seen with 73 of these sera, and was seen with undiluted serum or serum diluted 1:2 in another 16 sera In only 1 instance was specific nuclear fluorescence seen when the serum was diluted 1:4

51 patients with S L E were studied When the first serum drawn from each of these patients was examined, specific nuclear fluorescence was found with serum diluted 1:4 or higher in 45 In all, 151 specimens of serum from these 51 patients have been examined to date, and specific nuclear fluorescence with serum diluted 1:4 or higher was observed with 131 specimens As antinuclear factors were found when the serum was diluted 1:4 in only 1 of 90 sera examined as controls, the demonstration of antinuclear factors in serum diluted 1:4 or more appeared to distinguish patients with S L E from healthy subjects and those with a variety of other diseases The test was therefore called positive when antinuclear factors were demonstrated in serum diluted 1:4 or more

TABLE II—RESULTS OF TESTS FOR ANTINUCLEAR FACTORS IN THE RELATIVES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Relationship	Female relatives		Male relatives	
	Positive tests	Negative tests	Positive tests	Negative tests
Parents	5	1	0	4
Siblings	6	4	4	5
Offspring	2	0	2	3
Maternal siblings	3	1	1	1
First cousins	1	0	0	1
Grandparents	0	3	0	3
Totals	17	9	7	17

Single serum samples from 50 members of families of 12 patients with S L E were studied (tables I and II) Specific nuclear fluorescence was demonstrated with serum diluted 1:4 or more in 24 instances Positive tests were found with the sera of 19 of 36 first-degree relatives tested, and with the sera of 5 of 14 second-degree relatives Positive tests were found in 17 of 26 female relatives but in only 7 of 24 male relatives The difference in the frequency of positive tests in male and female relatives is significant ($\chi^2 = 5{\cdot}2$, P = < 0·05), but further observations on this difference are necessary

Two family pedigrees are shown in fig

In the first pedigree the propositus (II 4) w a 15-year-old schoolgirl in whom defin clinical evidence of S L E had been found, an in the past, Hargraves' cells had been demonstrated in her blood Findings diagnostic o lupus nephritus were observed in a renal biops 4 specimens of serum were tested for antinuclear factors when the patient was symptom-free as a result of treatment with prednisone, all were negative Positive tests for antinuclear factors were found in the mother (I 1) and 3 of 5 siblings—in 1 of whom (II 1) the titre was 1:1024

In the second pedigree the propositus (II 2) was a 21-year-old American Negro housewife with typical S L E Positive tests for antinuclear factors were found in the serum of the patient, her 2 younger sisters, her 5-year-old son, and 3-year-old daughter (III 3)—in whom the titre of antinuclear factors was 1:4096

The serum-γ-globulin levels were estimated by the Biuret reagent and filterpaper electrophoresis They are compared in fig 2 with values from 62 healthy Caucasian (1·13±0·23 g per 100 ml) and 62 healthy American Negro subjects (1·37±0·30 g per 100 ml) Elevated γ-globulin levels (>2 S D above the mean of the controls) were found in only 3 Caucasian relatives and 2 Caucasian controls Decreased γ-globulin levels (>2 S D below the mean of the controls) were found in 1 Caucasian and 2 Negro relatives 5 of the 6 Negro relatives were members of one family (pedigree 2) The difference between the γ-globulin levels in the members of this family and those in the controls was significant ($\chi^2 = 17{\cdot}2$, P = < 0·01)

DISCUSSION

In 1957 Leonhardt [2] reported S L E in 3 of 14 siblings He pointed out that at that time there were only four reported instances of the familial occurrence of S L E

Subsequently, Agranat et al [3] Larsson and Leonhardt,[4] and Lawrence [5] have each reported S L E in 2 sisters Wagenhals and Burgeson [6] observed the disease in twin sisters Griffin et al [7] found S L E in a father and his daughter, and Holman and Deicher [8] reported its occurrence in a mother and her daughter These clinical observations suggested that S L E may possibly be a familial disorder

In a study of two pedigrees, Larsson and Leonhardt [4] found higher mean serum-γ-globulin levels in siblings of patients with S L E and their children than in controls living under the same environmental conditions The siblings had higher mean γ-globulin values than the first cousins, and the siblings' children than the second cousins Larsson and Leonhardt considered that familial hypergammaglobulinæmia and familial S L E were possibly closely related and were *manifestations of* an underlying, genetically determined tendency to overproduction of γ-globulin Holman and Deicher [8] found " distinct hypergammaglobulinæmia " in 11 of 57 relatives from 18 families of patients with S L E , and Rodnan et al [9] found *definite* hypergammaglobulinæmia in 12 of 59 relatives, thus confirming the observations of Larsson and Leonhardt

9 Rodnan G P Maclachlan M J, Creighton, A S *Clin Res* 1960, 8, 197

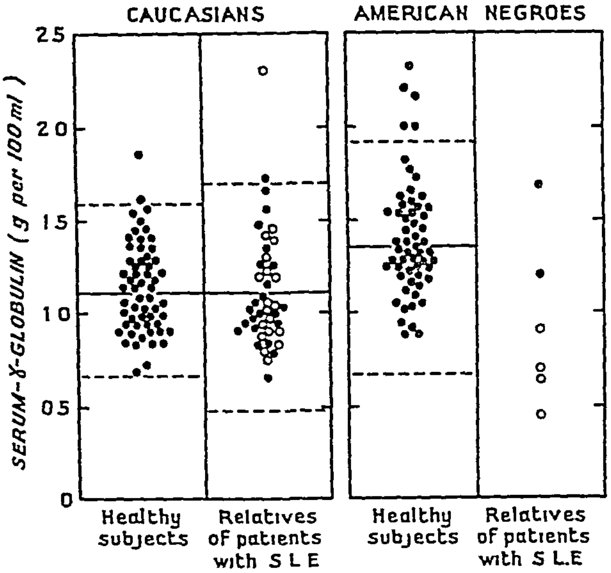

Fig 2.—Serum-γ-globulin levels in healthy subjects and in relatives of patients with S.L.E.

The mean values are given by continuous lines and two standard deviations by interrupted lines

○ = patients with positive tests for antinuclear factors
● = patients with negative tests for antinuclear factors

We found few relatives with hypergammaglobulinæmia, but somewhat high γ-globulin levels were found in 5 of 7 members of pedigree 1 Unusually low γ-globulin levels were found in 4 of 5 members of pedigree 2 This finding is of interest in view of the reported development of an arthritis resembling rheumatoid arthritis in almost half of 16 children with the congenital form of agammaglobulinæmia, and of collagen disease in patients with congenital and acquired agammaglobulinæmia [10]

The most striking abnormality found was the high prevalence of positive tests for antinuclear factors in the serum of relatives of patients with S.L E The results strongly suggest that an abnormal protein or proteins with an affinity for cell nuclei in vitro are present in the serum of about half the relatives By contrast, positive tests for antinuclear factors were found in the serum of only 1 of 50 subjects with diseases unrelated to S L E and in none of the 40 healthy subjects studied Hargraves' cells have been reported in about 12% of patients with rheumatoid arthritis [11] and occasionally in other so-called collagen diseases We found positive tests for antinuclear factors in the serum of only 5 of 35 patients with these disorders Thus the prevalence of positive tests for antinuclear factors was considerably higher in relatives of patients with S L E than in patients with rheumatoid arthritis, scleroderma, and dermatomyositis As rheumatoid arthritis and positive serological tests for rheumatoid factor appear to be commoner in relatives of patients with S L E that in the general population,[8] [9] relatives of patients with S L E may possibly comprise at least a proportion of the patients with clinical rheumatoid arthritis and positive Hargraves' cells or antinuclear factors

The ætiology of systemic lupus erythematosus is still unknown In recent years abundant evidence has been accumulated that the serum of patients with S L E contains several abnormal γ-globulins These abnormal γ-globulins, which react with cells or cell constituents in vitro, can probably be classified as auto-immune antibodies Patients with S L E also show increased responsiveness to foreign antigens [12] The mechanism underlying the appearance of autoimmune antibodies and the increased sensitivity to foreign antigens is still poorly understood Both these abnormalities, however, point to a derangement in the system regulating "immunological homœstasis" The data reported here indicate that this derangement probably has an hereditary basis, and suggest that overt disease may result from exposure to various antigens and other provocative stimuli in persons with the appropriate hereditary abnormality in the homœstasis of the antibody-producing system

We wish to thank Mrs Anne Doig, Mrs Janet Rezaian, and Mr Marcellus Moore for technical assistance This study was supported in part by a grant (H2253) from the United States Public Health Service, National Institutes of Health, Bethesda, Maryland

BLOOD-GROUP DISTRIBUTION IN MEGALOBLASTIC ANÆMIA OF PREGNANCY

FOLIC-ACID deficiency in pregnancy is characterised by the appearance of megaloblasts in the marrow In the most severe cases these are of the classical Ehrlich type, as seen in addisonian anæmia, whereas transitional megaloblasts are encountered in the milder forms of the disease More recent studies have shown that folic-acid depletion frequently occurs in late pregnancy without producing megaloblastic changes in the marrow,[13] although the hæmoglobin-level can generally be raised by the administration of folic acid [14]

Folic-acid deficiency in pregnancy can thus be conveniently classified in four categories

Grade 0—The marrow remains entirely normoblastic and folic-acid depletion can be diagnosed with certainty only by folic-acid assays In these cases the hæmoglobin level can usually be raised by folic-acid therapy

Grade 1—The mildest form of megaloblastic anæmia, in which the marrow is predominantly normoblastic, though it contains a number of transitional megaloblasts Diagnosis in such cases may need confirmation by other criteria—e g, a raised serum-iron level and satisfactory response to folic-acid therapy

Grade 2—The marrow is predominantly megaloblastic, but the majority of cells is of the transitional type.

Grade 3—A florid megaloblastic marrow in which the classical Ehrlich type of megaloblast predominates The marrow picture in these cases is indistinguishable from that seen in addisonian anæmia

Obviously, the marrow-changes in these four categories reflect, to some extent, the degree of folic-acid depletion in any given person It would be an oversimplification to assume from this that all pregnant women with folic-acid

diseases unrelated to S L E were studied as controls Specific nuclear fluorescence was not seen with 73 of these sera, and was seen with undiluted serum or serum diluted 1 2 in another 16 sera In only 1 instance was specific nuclear fluorescence seen when the serum was diluted 1 4

51 patients with S L E were studied When the first serum drawn from each of these patients was examined, specific nuclear fluorescence was found with serum diluted 1 4 or higher in 45 In all, 151 specimens of serum from these 51 patients have been examined to date, *and specific nuclear fluorescence with serum diluted 1 4* or higher was observed with 131 specimens As antinuclear factors were found when the serum was diluted 1 4 in only 1 of 90 sera examined as controls, the demonstration of antinuclear factors in serum diluted 1 4 or more appeared to distinguish patients with S L E from healthy subjects and those with a variety of other diseases The test was therefore called positive when antinuclear factors were demonstrated in serum diluted 1 4 or more

TABLE II—RESULTS OF TESTS FOR ANTINUCLEAR FACTORS IN THE RELATIVES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHMATOSUS

Relationship	Female relatives		Male relatives	
	Positive tests	Negative tests	Positive tests	Negative tests
Parents	5	1	0	4
Siblings	6	4	4	5
Offspring	2	0	2	3
Maternal siblings	3	1	1	1
First cousins	1	0	0	1
Grandparents	0	3	0	3
Totals	17	9	7	17

Single serum samples from 50 members of families of 12 patients with S L E were studied (tables I and II) Specific nuclear fluorescence was demonstrated with serum diluted 1 4 or more in 24 instances *Positive tests* were found with the sera of 19 of 36 first-degree relatives tested, and with the sera of 5 of 14 second-degree relatives Positive tests were found in 17 of 26 female relatives but in only 7 of 24 male relatives The difference in the frequency of positive tests in male and female relatives is significant (χ^2=5 2, P= <0 05), but further observations on this sex difference are necessary

Two family pedigrees are shown in fig 1

In the first pedigree the propositus (II 4) was a 15-year-old schoolgirl in whom definite clinical evidence of S L E had been found, and, in the past, Hargraves cells had been demonstrated in her blood Findings diagnostic of lupus nephritis were observed in a renal biopsy 4 specimens of serum were tested for antinuclear factors when the patient was symptom-free as a result of treatment with prednisone, all were negative Positive tests for antinuclear factors were found in the mother (I 1) and 3 of 5 siblings—in 1 of whom (II 1) the titre was 1 1024

In the second pedigree the propositus (II 2) was a 21-year-old American Negro housewife with typical S L E Positive tests for antinuclear factors were found in the serum of the patient, her 2 younger sisters, her 5-year-old son, and 3-year-old daughter (III 3)—in whom the titre of antinuclear factors was 1 4096

The serum-γ-globulin levels were estimated by the Biuret reagent and filterpaper electrophoresis They are compared in fig 2 with values from 62 healthy Caucasian (1 13±0 23 g per 100 ml) and 62 healthy American Negro subjects (1 37±0 30 g per 100 ml) Elevated γ-globulin levels (>2 S D above the mean of the controls) were found in only 3 Caucasian relatives and 2 Caucasian controls Decreased γ-globulin levels (>2 S D below the mean of the controls) were found in 1 Caucasian and 2 Negro relatives 5 of the 6 Negro relatives were members of one family (pedigree 2) The difference between the γ-globulin levels in the members of this family and those in the controls was significant (χ^2=17 2, P= <0 01)

DISCUSSION

In 1957 Leonhardt [2] reported S L E in 3 of 14 siblings He pointed out that at that time there were only four reported instances of the familial occurrence of S L E

Subsequently, Agranat et al [3] Larsson and Leonhardt,[4] and Lawrence [5] have each reported S L E in 2 sisters Wagenhals and Burgeson [6] observed the disease in twin sisters Griffin et al [7] found S L E in a father and his daughter, and Holman and Deicher [8] reported its occurrence in a mother and her daughter These clinical observations suggested that S L E may possibly be a familial disorder

In a study of two pedigrees, Larsson and Leonhardt [4] found higher mean serum-γ-globulin levels in siblings of patients with S L E and their children than in controls living under the same environmental conditions The siblings had higher mean γ-globulin values than the first cousins, and the siblings' children than the second cousins Larsson and Leonhardt considered that familial hypergammaglobulinæmia and familial S L E were possibly closely related and were manifestations of an underlying, genetically determined tendency to over-production of γ-globulin Holman and Deicher [8] found " distinct hypergammaglobulinæmia " in 11 of 57 relatives from 18 families of patients with S L E, and Rodnan et al [9] found definite hypergammaglobulinæmia in 12 of 59 relatives, thus confirming the observations of Larsson and Leonhardt

We found few relatives with hypergammaglobulinæmia, but somewhat high γ-globulin levels were found in 5 of 7 members of pedigree 1. Unusually low γ-globulin levels were found in 4 of 5 members of pedigree 2. This finding is of interest in view of the reported development of an arthritis resembling rheumatoid arthritis in almost half of 16 children with the congenital form of agammaglobulinæmia, and of collagen disease in patients with congenital and acquired agammaglobulinæmia.[10]

The most striking abnormality found was the high prevalence of positive tests for antinuclear factors in the serum of relatives of patients with S.L.E. The results strongly suggest that an abnormal protein or proteins with an affinity for cell nuclei in vitro are present in the serum of about half the relatives. By contrast, positive tests for antinuclear factors were found in the serum of only 1 of 50 subjects with diseases unrelated to S.L.E. and in none of the 40 healthy subjects studied. Hargraves' cells have been reported in about 12% of patients with rheumatoid arthritis[11] and occasionally in other so-called collagen diseases. We found positive tests for antinuclear factors in the serum of only 5 of 35 patients with these disorders. Thus the prevalence of positive tests for antinuclear factors was considerably higher in relatives of patients with S.L.E. than in patients with rheumatoid arthritis, scleroderma, and dermatomyositis. As rheumatoid arthritis and positive serological tests for rheumatoid factor appear to be commoner in relatives of patients with S.L.E. that in the general population,[8] [9] relatives of patients with S.L.E. may possibly comprise at least a proportion of the patients with clinical rheumatoid arthritis and positive Hargraves' cells or antinuclear factors.

The ætiology of systemic lupus erythematosus is still unknown. In recent years abundant evidence has been accumulated that the serum of patients with S.L.E. contains several abnormal γ-globulins. These abnormal γ-globulins, which react with cells or cell constituents in vitro, can probably be classified as auto-immune antibodies. Patients with S.L.E. also show increased responsiveness to foreign antigens.[12] The mechanism underlying the appearance of autoimmune antibodies and the increased sensitivity to foreign antigens is still poorly understood. Both these abnormalities, however, point to a derangement in the system regulating "immunological homœstasis." The data reported here indicate that this derangement probably has an hereditary basis, and suggest that overt disease may result from exposure to various antigens and other provocative stimuli in persons with the appropriate hereditary abnormality in the homœstasis of the antibody-producing system.

We wish to thank Mrs Anne Doig, Mrs Janet Rezaian, and Mr Marcellus Moore for technical assistance. This study was supported in part by a grant (H2253) from the United States Public Health Service, National Institutes of Health, Bethesda, Maryland.

BLOOD-GROUP DISTRIBUTION IN MEGALOBLASTIC ANÆMIA OF PREGNANCY

FOLIC-ACID deficiency in pregnancy is characterised by the appearance of megaloblasts in the marrow. In the most severe cases these are of the classical Ehrlich type, as seen in addisonian anæmia, whereas transitional megaloblasts are encountered in the milder forms of the disease. More recent studies have shown that folic-acid depletion frequently occurs in late pregnancy without producing megaloblastic changes in the marrow,[13] although the hæmoglobin-level can generally be raised by the administration of folic acid.[14]

Folic-acid deficiency in pregnancy can thus be conveniently classified in four categories:

Grade 0.—The marrow remains entirely normoblastic and folic-acid depletion can be diagnosed with certainty only by folic-acid assays. In these cases the hæmoglobin level can usually be raised by folic-acid therapy.

Grade 1.—The mildest form of megaloblastic anæmia, in which the marrow is predominantly normoblastic, though it contains a number of transitional megaloblasts. Diagnosis in such cases may need confirmation by other criteria—e.g., a raised serum-iron level and satisfactory response to folic-acid therapy.

Grade 2.—The marrow is predominantly megaloblastic, but the majority of cells is of the transitional type.

Grade 3.—A florid megaloblastic marrow in which the classical Ehrlich type of megaloblast predominates. The marrow picture in these cases is indistinguishable from that seen in addisonian anæmia.

Obviously, the marrow-changes in these four categories reflect, to some extent, the degree of folic-acid depletion in any given person. It would be an oversimplification to assume from this that all pregnant women with folic-acid

Reviews of Books

Medical and Dental Aspects of Fluoridation

W A Cannell, M R C S, D P H, L D S London Lewis 1960 Pp 125 15*s*

Most of the growing literature of fluoridation and fluorine is scattered in various journals A great deal of the research has been done in the United States, and the few books that have appeared since Roholm's classic text in 1937 have been published there A British survey of the present state of knowledge is welcome, and Dr Cannell gives a concise and readable summary, with an account of some important original work on the effect of trace elements

It is a relief to find a book that deliberately does not discuss the various fluoridation trials in the United States So much has been written about them and their real and alleged shortcomings that there is a risk of losing sight of one of the fundamental issues—the physiological and biochemical effects of fluorides Too little is generally known about the systemic effects of fluorides, and Dr Cannell's book should go a long way towards dispelling this ignorance, especially among the opponents of fluoridation

The chapters on the pharmacology of the fluorides and on the calcification of skeletal and dental tissues are particularly good Speculation is kept to a minimum, and the facts are presented fairly, and without bias Not everyone will agree with Dr Cannell in his excursion into the field of logical causality (p 69), but the inescapability of fluorides renders his argument an attractive one

The final chapter, on the public-health aspects, puts forward a well-reasoned case for the fluoridation of water-supplies Other possible means of administration are discussed in the light of recent research The bibliography is comprehensive and up to date, though there is no reference to Mackenzie's extensive review[1]

This is probably one of the best accounts of fluorides and their effects that has been published for some time

Pathology of Infancy and Childhood

Agnes R Macgregor, M D, F R C P E, F R C O G, reader in pathology, Edinburgh University Edinburgh and London E & S Livingstone 1960 Pp 631 75*s*

A volume concerned entirely with pædiatric pathology has been urgently needed by many pathologists, and the gap has been partly filled by this book in which Dr Macgregor incorporates the experience of her many years as an authority on this subject It is a simple book it makes no pretension to being a work of reference for pædiatric pathologists, but has been designed for the pathologist whose main work and interests are with older patients Most conditions which he is likely to meet are considered adequately, with proper regard for their relative importance and incidence Bearing in mind that the great majority of necropsies are on infants dying in the perinatal period, notes on necropsy technique and detailed practical accounts of perinatal conditions are included Many facts in this part of the book rarely appear in print and are usually appreciated only after considerable experience The section dealing with developmental anomalies could have been fortified by the inclusion of notes on embryology, supported by diagrams Since many hospitals have cardiothoracic units, and deaths from cardiovascular anomalies often form a big part of pædiatric necropsy work, the account of these anomalies may be too superficial Although the photographs of specimens of malformed hearts are generally self-explanatory, a few diagrams would have enhanced clarity A lack of uniformity between different sections of the book is mainly due to the omission of conditions which are not peculiar to infants or children, or which are well described in standard textbooks of pathology But a few relatively important diseases are treated rather briefly, and many less common conditions are not mentioned even by reference to the literature Although the references are well chosen and up to date, the bibliography will be little help to the pathologist faced with an unusual case

This book will be particularly useful to those embarking upon a career in pathology or pædiatrics Its value to the established pathologist is limited, but it will be enjoyed by those who appreciate the signs of the author's wide experience

The Chemical Senses in Health and Disease

H Kalmus, SC D, M D, reader in biology, University of London, S J Hubbard, B SC, PH D, lecturer in physiology, University College, London Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1960 Pp 95 30*s*

No disciple of Brillat-Savarin needs to be reminded of the importance of the chemical senses—concerned as they are with taste and smell But many may be surprised at the complexity of the physiological processes subserving the art of transcendental gastronomy Who would have suspected, for instance, that over 60 volatile substances contribute to the aroma of coffee? This suggests almost endless permutation of naturally occurring odours and many kinds of odour-receptors On the other hand, only four basic tastes—sour, salt, sweet, and bitter—are firmly established The interplay of taste and smell, the importance of these chemical senses in behaviour both in animals and man, some curious and interesting genetical variations in both senses, and lines of future research and their practical importance are all discussed in this book The psychological aspects—in some ways the most fascinating of any—are also briefly mentioned The book is short and well worth the attention of physiologist and clinician It is a pity the price is so high

The Early History of Surgery

W J Bishop, editor, *Medical History* London Robert Hale 1960 Pp 192 18*s*

At a time when road travel is becoming increasingly dangerous, it is good to discover that some at least of its former hazards have been mitigated Richard Wiseman, writing in 1676, described the misadventure which befell " a gentleman of about thirty years of age, who was coming out of Hertfordshire through Tottenham and riding upon the causeway near an inn when, one emptying a chamber pot out of the window deficiency are equally liable to develop advanced megaloblastic anæmia. A study of the blood-group distribution of patients with megaloblastic anæmia of pregnancy has shown that cases with a grade-3 type of marrow, in which the classical Ehrlich type of megaloblasts are encountered, probably represent a special group which appears to be genetically determined.

---

[1] Mackenzie E F W *Lancet*, 1952 i 961

The blood-group distribution of 175 patients with megaloblastic anæmia of pregnancy was compared with that of 3500 routine antenatal cases in the same district*. As seen in table I, the only deviation from the norm is an increase in the incidence of blood-group A in patients with megaloblastic anæmia, but this is less than the group A preponderance reported in addisonian anæmia.[15]

TABLE I—BLOOD-GROUP DISTRIBUTION IN MEGALOBLASTIC ANÆMIA OF PREGNANCY*

Blood group	Routine antenatal (3500 cases)	Megaloblastic anæmia of pregnancy			
		All grades (175 cases)	grade 3 (77 cases)	grade 2 (59 cases)	grade 1 (39 cases)
O	46%	43%	34%	48%	56%
A	42%	50%	60%	46%	36%
B	9%	5%	5%	3%	5%
AB	3%	2%	1%	3%	3%

When, however, cases of megaloblastic anæmia of pregnancy were classified according to their hæmatological grade (from 1 to 3), and the blood-group distribution calculated separately for each grade, it became obvious that there was only one category with a definite group-A preponderance—namely, grade 3—composed of those cases in which the marrow most closely resembles that of addisonian anæmia. Table I shows that the incidence of blood-group A in 77 cases in category 3 is 60%, compared with a proportion of 42% in the controls. As seen in table II, this difference is statistically significant ($P < 0.01$). On the other hand, the group-A incidence in those patients who were classified in grades 1 and 2 is 42%, which closely approaches the normal distribution.

TABLE II—INCIDENCE OF GROUP-A IN MEGALOBLASTIC ANÆMIA OF PREGNANCY

Megaloblastic anæmia of pregnancy	Number of cases	Group A incidence	χ^2	P
All grades	175	50%	4.18	<0.05
Grade 3	77	60%	9.16	<0.01
Grade 2	59	46%	0.30	>0.5
Grade 1	39	36%	0.43	>0.5
Grades 1 and 2	98	42%	0.04	>0.5
Controls	3500	42%		

Analysis of clinical and hæmatological findings in women with the various grades of megaloblastic anæmia shows that grade-3 cases tend to present with more severe anæmia, higher serum-iron levels, and usually show a greater reticulocyte response to folic-acid therapy. In other respects, patients in the various categories do not appear to differ. Their age-distribution is similar and the incidence of achlorhydria is approximately the same. A history of an inadequate diet in pregnancy appears with equal frequency in all categories, and the previous administration of iron does not seem to affect the marrow-picture. Gastrointestinal symptoms, especially anorexia and ulceration of the mouth, occur equally often with lesser degrees of megaloblastosis.

It would obviously be premature to draw definite conclusions from the blood-group distribution in a single series of cases from one district. These findings suggest, however, that while folic-acid deficiency, with or without megaloblastic changes in the marrow, is a frequent occurrence in late pregnancy, patients with advanced megaloblastic anæmia constitute a special group in which there is an inherited predisposition to the disease. The report by Giles and Burton[14] of 13 out of 41 cases of megaloblastic anæmia of pregnancy, with evidence of diminished fat absorption, has already pointed to a constitutional factor in the ætiology of the disease. It is perhaps significant that a grade-3 type of marrow was found in 10 of these 13 cases.

My thanks are due to Mr. A. H. Iliffe, of the University College of North Staffordshire, for the statistical analysis, to Dr. R. B. McConnell for his helpful advice, to Dr. A. J. McCall for his help and encouragement, and to the research fund of the Birmingham Regional Hospital Board for its assistance.

New Inventions

A HEART-LUNG MACHINE FOR INFANTS AND YOUNG CHILDREN

MOST heart-lung machines are designed for patients of 3 to 5 years and over. Moreover, particular attention has been directed towards apparatus capable of maintaining the circulation in full-sized adults. A number of congenital defects are responsible for death within the first year of life[1], but existing machines, with their relatively large priming volume, are not readily adaptable to the low flows and blood-volumes in this age-group.

The following heart-lung circuit has been designed to provide flows up to 1.2 litres per min., with a priming volume of 500–750 ml.

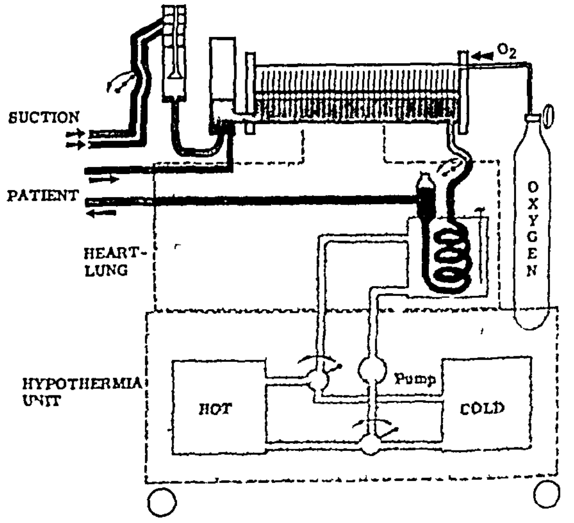
Apparatus

Basically this is a scaled-down version of the model in current clinical use.[2] The oxygenator is of the rotating disc variety, and a heat-exchanger is included in the circuit. The apparatus is entirely self-contained, being provided with its own source of heating and cooling fluids (see figure).

Two complete oxygenators are available (22 and 34 cm. long). The smaller provides for flows up to 700 ml. per min., and the larger for flows up to 1200 ml. per min. The discs are of stainless steel, 7.8 cm. in diameter and spaced 4 mm. apart. Spacing of the discs at less than 4 mm. causes foaming. No silicone or anti-foam is required in the oxygenator. The rotation speed of the discs is 120 r.p.m.

---

1. Bonham Carter, R. E., Waterston, D. J. *Brit. Heart J.* 1957, 19, 589.
2. Ross, D. N. *Brit. med. J.* 1960, ii, 571.



Circuit diagram of the complete apparatus showing the hypothermia unit below.

Cooling and rewarming is by means of a heat-exchanger constructed from stainless steel. A filter and bubble trap are incorporated in the arterial outflow line. Two sucker lines are provided which deliver their blood on to five perforated plates lightly coated with anti-foam. The output of the arterial pump and of the pump controlling the suction lines can be varied by two simple hand controls. The apparatus and tubing in contact with blood is sterilised in ethylene oxide for 24 hours before use.

The hypothermic and heating equipment is contained within a low trolley which acts as a mount for the heart-lung machine. In this way the apparatus, while remaining compact, is entirely self-contained. The cold source is supplied with a mixture of ice and water kept in a lagged 2 gal. tank, and hot water is kept thermostatically controlled at about 40°C in a separate tank.

Application

The apparatus has been used in twenty-five dog experiments. In addition, four children have been operated on, with one death. In use the machine requires very little adjustment, the running being in the hands of one technician.

The apparatus has been constructed for me by Mr. A. F. Turner in the Guy's Hospital Medical School workshop, and it will be available through Cardiac Recorders, Ltd., Weymouth Street, London, W.1.

Reviews of Books

Medical and Dental Aspects of Fluoridation

W. A. CANNELL, M.R.C.S., D.P.H., L.D.S. London: Lewis. 1960. Pp. 125. 15s.

MOST of the growing literature of fluoridation and fluorine is scattered in various journals. A great deal of the research has been done in the United States, and the few books that have appeared since Roholm's classic text in 1937 have been published there. A British survey of the present state of knowledge is welcome, and Dr. Cannell gives a concise and readable summary, with an account of some important original work on the effect of trace elements.

It is a relief to find a book that deliberately does not discuss the various fluoridation trials in the United States. So much has been written about them and their real and alleged shortcomings that there is a risk of losing sight of one of the fundamental issues—the physiological and biochemical effects of fluorides. Too little is generally known about the systemic effects of fluorides, and Dr. Cannell's book should go a long way towards dispelling this ignorance, especially among the opponents of fluoridation.

The chapters on the pharmacology of the fluorides and on the calcification of skeletal and dental tissues are particularly good. Speculation is kept to a minimum, and the facts are presented fairly, and without bias. Not everyone will agree with Dr. Cannell in his excursion into the field of logical causality (p. 69), but the inescapability of fluorides renders his argument an attractive one.

The final chapter, on the public-health aspects, puts forward a well-reasoned case for the fluoridation of water-supplies. Other possible means of administration are discussed in the light of recent research. The bibliography is comprehensive and up to date, though there is no reference to Mackenzie's extensive review.[1]

This is probably one of the best accounts of fluorides and their effects that has been published for some time.

Pathology of Infancy and Childhood

AGNES R. MACGREGOR, M.D., F.R.C.P.E., F.R.C.O.G., reader in pathology, Edinburgh University. Edinburgh and London: E. & S. Livingstone. 1960. Pp. 631. 75s.

A VOLUME concerned entirely with pædiatric pathology has been urgently needed by many pathologists, and the gap has been partly filled by this book in which Dr. Macgregor incorporates the experience of her many years as an authority on this subject. It is a simple book: it makes no pretension to being a work of reference for pædiatric pathologists, but has been designed for the pathologist whose main work and interests are with older patients. Most conditions which he is likely to meet are considered adequately, with proper regard for their relative importance and incidence. Bearing in mind that the great majority of necropsies are on infants dying in the perinatal period, notes on necropsy technique and detailed practical accounts of perinatal conditions are included. Many facts in this part of the book rarely appear in print and are usually appreciated only after considerable experience. The section dealing with developmental anomalies could have been fortified by the inclusion of notes on embryology, supported by diagrams. Since many hospitals have cardiothoracic units, and deaths from cardiovascular anomalies often form a big part of pædiatric necropsy work, the account of these anomalies may be too superficial. Although the photographs of specimens of malformed hearts are generally self-explanatory, a few diagrams would have enhanced clarity. A lack of uniformity between different sections of the book is mainly due to the omission of conditions which are not peculiar to infants or children, or which are well described in standard textbooks of pathology. But a few relatively important diseases are treated rather briefly, and many less common conditions are not mentioned even by reference to the literature. Although the references are well chosen and up to date, the bibliography will be little help to the pathologist faced with an unusual case.

This book will be particularly useful to those embarking upon a career in pathology or pædiatrics. Its value to the established pathologist is limited, but it will be enjoyed by those who appreciate the signs of the author's wide experience.

The Chemical Senses in Health and Disease

H. KALMUS, SC.D., M.D., reader in biology, University of London; S. J. HUBBARD, B.SC., PH.D., lecturer in physiology, University College, London. Springfield, Ill.: Charles C Thomas. Oxford: Blackwell Scientific Publications. 1960. Pp. 95. 30s.

NO disciple of Brillat-Savarin needs to be reminded of the importance of the chemical senses—concerned as they are with taste and smell. But many may be surprised at the complexity of the physiological processes subserving the art of transcendental gastronomy. *Who would have suspected, for* instance, that over 60 volatile substances contribute to the aroma of coffee? This suggests almost endless permutation of naturally occurring odours and many kinds of odour-receptors. On the other hand, only four basic tastes—sour, salt, sweet, and bitter—are firmly established. The interplay of taste and smell, the importance of these chemical senses in behaviour both in animals and man, some curious and interesting genetical variations in both senses, and lines of future research and their practical importance are all discussed in this book. The psychological aspects—in some ways the most fascinating of any—are also briefly mentioned. The book is short and well worth the attention of physiologist and clinician. It is a pity the price is so high.

The Early History of Surgery

W. J. BISHOP, editor, *Medical History*. London: Robert Hale. 1960. Pp. 192. 18s.

AT a time when road travel is becoming increasingly dangerous, it is good to discover that some at least of its former hazards have been mitigated. Richard Wiseman, writing in 1676, described the misadventure which befell "a gentleman of about thirty years of age, who was coming out of Hertfordshire through Tottenham and riding upon the causeway near an inn when, one emptying a chamber pot out of the window

as he was passing by, his horse started and rushed violently between a signpost and a tree which supported part of the sign The poor gentleman was beaten off his horse and lay stunned upon the ground " This case, and Wiseman's successful management of it, is one of the many which Mr Bishop uses to illustrate the evolution of surgery His book is happily written in a style easily intelligible to the layman, yet technical enough to appeal to doctors as well, and, as might be expected from the author's status as an antiquarian, it is distinguished by a meticulous attention to accuracy Even in such a matter as the emergency operation on King Edward VII, it is noted that it was never officially stated whether or not an appendicectomy had been performed

The Healthy Child

His Physical, Psychological, and Social Development Editors HAROLD C STUART, M D, emeritus professor of maternal and child health, Harvard University School of Public Health, DANE G PRUGH, M D, associate professor of pædiatrics and psychiatry, University of Rochester School of Medicine and Dentistry Cambridge, Mass Harvard University Press London Oxford University Press 1960 Pp 507 80*s*

THIS book is written for all who work professionally with children, whether in the areas of medicine, education, social work, public health, nutrition, nursing, or psychology, and those who have contributed to it come from a correspondingly wide range of disciplines The emphasis is on " healthy development " and how it may best be protected or promoted The book presents in broad terms a picture of the child and his expected progress from conception to maturity It is concerned with him as an individual who is changing or developing according to natural laws and inborn potentialities It deals with the major aspects of his physical development and also with his psychosocial development and the factors which favour mental health Among its many interesting chapters is one on emotional changes in pregnancy Emphasising throughout the wide range of normal, the book is a valuable contribution to the increasing literature on the important subject of normality

Life's Long Journey

KENNETH WALKER, F R C S London Victor Gollancz 1960 Pp 191 21*s*

Mr Kenneth Walker writes, for the general public, to discount excessive claims for the material sciences in general, and in particular the supposition that natural selection sufficiently explains the course of human evolution and that scientific control could or should direct its future course, if any

In the earlier chapters he seems to postulate " life " as a forward-looking entity planning its own development, but throughout the book " Nature ", without inverted commas, appears as experimenter and giver or withholder of gifts, and it is not at all clear whom or what he regards as the " eternal mover ", though he makes a firm claim for the life spiritual and the reality of mystical experience

Like some others, Mr Walker regards the present population explosion as more dangerous to humanity than the atom bomb and fears our despairing recourse to Communist termitism He is surely unjust to Ecclesiastes (" cast thy bread upon the waters ") in ascribing to him and not to Proverbs the advice to look to the ant for exemplar, but that, in the present human predicament, the termitary is terrifying to contemplate is sure enough

No Crying in this Cradle

The Expectant and Nursing Mother's Bedside Book ELIZABETH G MORRISON, S R N, S C M, M T S, JOAN GOLDMAN London Ernest Benn 1960 Pp 159 15*s*

Elizabeth Morrison has had a vast experience of reading and answering letters from mothers because for thirty years she has run the correspondence columns in *Nursery World* But one wonders just how much practical experience she has had, and how recently Some of the advice she gives is outdated—e g, " it is advisable to go specially easy on meat in the last month or two of pregnancy " There seems little point in advising an expectant mother not to eat mixed grill and telling her that it won't make her or the baby " *feel too good* " The book says that eiderdowns for babies "ought to be forbidden by an Act of Parliament ", not because they may smother the baby, but because " *nothing more effective exists to make the baby sweat* " Most of the book is an invective in favour of breast-feeding But the reasons why babies should be breast-fed whenever possible are poorly argued and unconvincing It is true that some doctors do not know much about normal babies, but it is doubtful whether many are as woefully ignorant as this book suggests Doubtless dissatisfied patients write in sorrow and anger to the magazines, and Sister Morrison must receive many such letters But to describe the doctor and baby clinic as " statistics-ridden prophets " who " yell the roof off with their denunciations " seems to be going rather far

Nevertheless, the book contains a good deal of sensible, practical advice of the kind that is being given daily by good doctors and nurses up and down the country

Clinical Bacteriology (2nd ed London Edward Arnold 1960 Pp 309 30*s*)—The duties of the bacteriologist in a hospital are to isolate pathogenic bacteria, to decide from collateral evidence and probability that these have some connection with the patient's illness, and—a recent development—to give guidance on the treatment of the infection to those responsible for the patient The identity of the organism is not vastly important (except to the epidemiologist) but custom at least demands that this shall be reported as accurately as possible It is this academic pride in going beyond the bare diagnosis and treatment which distinguishes the medical bacteriologist from the technician When Dr Joan Stokes' book first appeared it was the best benchbook for the medical bacteriologist which had been published and it remains so today The academic background (for which she still apologises) converts what might have been a mere cookery book into a readable and reliable guide to work at the bench The changes in this second edition add some new methods and take account of some recent advances in knowledge, but as before it is clear that all the recommendations are made in the light of personal experience

Demonstrations of Physical Signs in Clinical Surgery (13th ed Bristol John Wright 1960 Pp 928 75*s*)—In 1927 medical illustration was just emerging from the era of line drawings Some textbooks contained a few photographs, but they were often reproduced in poorly contrasting shades of grey, and the technique of colour printing was in its infancy When, therefore, in that year, the first edition of this book appeared, with its clear and vivid illustrations, students were quick to appreciate the efforts that Mr Hamilton Bailey and his publishers had made on their behalf It comes as no surprise to learn that, of the English editions alone, 177,000 copies have now been sold The latest edition contains more than four times as many pages and illustrations as the first, and if this growth-rate is maintained the twenty-fifth edition may well include an illustration of the typical lesion the volume produces by resting on the reader's knees Many pictures have been furnished by distinguished clinicians, some of whom would no doubt acknowledge that they were helped to their first academic successes by the very work to which they have now contributed

Principles of Orthopædic Surgery (London J & A Churchill 1960 Pp 799 150*s*)—Dr Paul E Colonna earlier published a book based on his lectures and teaching-rounds at the University of Pennsylvania This volume is an expanded form (a notable difference is the increased space devoted to traumatic lesions) but has in common with the earlier one a style of writing and printing that makes for easy reading even over long periods A few of the radiographs are not adequately reproduced, but the work is one of the very few which can be freely quoted on either side of the Atlantic without modification and with equal authority

THE LANCET

LONDON 12 NOVEMBER 1960

Malaria Research

WHEN LAVERAN discovered the malaria parasite in 1880 he opened the flood gates to a torrent of research which, despite ebbs and flows, today runs as strongly as ever It seemed at various times that the problems of malaria had been finally solved at the end of the century when the mechanism of transmission through mosquitoes was worked out, the way seemed open (or so at least Ross thought) for the control and abolition of the disease, in the years between the wars, and later, a range of drugs was synthesised which seemed to offer the perfect therapy, then the researches on the exo-erythrocytic cycle from 1936 onwards had apparently filled the last gap in our knowledge of the life-cycle of the parasite, while the discovery of dicophane (D D T) and other residual insecticides was thought to have provided the final answer to the problem of mosquito eradication. And today, although we may feel that the end is in sight, this impression may be as false as any similar one expressed earlier in the century

The study of malaria involves so many disciplines that a special composite science—malariology—inevitably developed, with its own institutes, journals, techniques, jargon, and specially its cadre of international workers who have devoted their lives to this fascinating borderline of research The malariologist must be prepared to dabble in entomology and protozoology, in clinical medicine, in chemotherapy and biochemistry, in statistics and genetics, even in such uncongenial subjects as engineering, administration, and sociology An issue of the *Bulletin of the World Health Organisation* [1] illustrates something of this range. It includes a paper by Sir GORDON COVELL (who has been awarded the Walter Reed medal for services to tropical medicine) on the potential danger of apyrexial carriers of malaria in constituting an unobvious reservoir of infection during eradication campaigns, an account by A. S ALVING (Chicago) of a new method of administering primaquine (the drug which destroys the exo-erythrocytic stages of the malaria parasite and prevents relapses) by reducing the toxicity of this invaluable drug, a complete analysis by L T BRUCE-CHWATT and C GOCKEL, of W.H.O, of the results of precipitin tests (carried out by B WEITZ, of the Lister Institute) of the stomach contents of anopheline mosquitoes, which showed that 48 out of 51 species fed to a greater or lesser extent on human blood, and other papers dealing with the action of dicophane and other residual insecticides R C MUIRHEAD-THOMSON, and G SACCA and Y GUY show how mosquitoes alter their habits after long exposure to dicophane—the so-called "behaviouristic resistance" The Colonial Pesticides Research Unit at Arusha suggests that the addition of a resin (ceredor) to gamma benzene hexachloride has provided the ideal insecticide for malaria control

Current research in malariology is as eclectic as ever Fundamental studies on the life-cycle of the parasite have been facilitated by using chimpanzees instead of volunteers, and BRAY [2] in Liberia, after finding that the liver of this ape is as susceptible as that of man to *Plasmodium vivax, ovale,* and *falciparum,* successfully demonstrated for the first time the tissue stages of the quartan parasite (*P malariæ*) by this technique There has been much controversy over the nature of nuclear division in malaria parasites, but BANO [3] has clearly demonstrated that the first division of the nucleus of the oocyst is meiotic, and that subsequent ones are mitotic, with a characteristic number of chromosomes in each of the seven species of plasmodia she studied The protective action of sickle-cell hæmoglobin against *P falciparum* was demonstrated by ALLISON [4] and other workers in 1954 and later More recently GILLES et al [5] have suggested that the possession of another hereditary trait—glucose-6-phosphate-dehydrogenase deficiency in red blood-cells—also has an inhibitory effect on the parasite.

Research on resistance has made much progress in the past few years In Algiers, SERGENT and PONCET [6] studied the development of resistance against chloroquine by *P berghei* in rats and mice, and introduced the term "mithridatism" for this feature The work of BISHOP [7] at the Molteno Institute went deeper and indicates that the resistance may have a mutational origin and be concerned with the metabolism of *p*-aminobenzoic acid and folic acid The resistance of several species of mosquitoes to insecticides presents a baffling problem in the eradication programme, and the genetic nature of this phenomenon has been shown at the Ross Institute, where DAVIDSON and JACKSON [8] demonstrated that resistance was of two independent types—to dicophane and dieldrin respectively, arising from single genetic factors, recessive in the former and semidominant in the latter, and applying to species of anopheline mosquitoes from as far apart as Africa, Indonesia, Iraq, and Central America This work has been confirmed to some extent by the cytological studies of FRIZZI and others [9] in Pavia, they have described in great detail the chromosome pattern of several species of mosquitoes, including susceptible and resistant forms These profound laboratory investigations stemmed directly from observations made in the field in Sokotu, Northern Nigeria, where RAMAKRISHNAN and ELLIOTT[10] noticed the sudden resistance to dieldrin of *Anopheles gambiæ* This is a good example of "incidental research", which has been a feature of malariology throughout its history

Animal malaria, which has excited interest from the earliest days, has attracted fresh attention through the discovery[11] in the U S A that a strain of monkey malaria, isolated in London, readily infects man The parasite was named after G BASTIANELLI, the last of the great band of Italian malariologists, who died last year at the age of 96 This organism was being studied in three laboratories in the U S A , and, in all three, accidental infections occurred through the bites of infected mosquitoes The disease proved to be mild, and clinically and parasitologically resembled benign tertian malaria Subsequently G R COATNEY, D E EYLES, M E GETZ, and H K BEYE transmitted the infection back to monkeys and to volunteers, both by mosquitoes and by inoculation of blood containing parasites It was at once realised that here at last was direct evidence that monkeys might act as a reservoir of malaria in Nature, and that this infection might constitute a zoonosis Previously it had been well established[12] that another monkey parasite—*P knowlesi*—could easily affect man in its blood form, but mosquito transmission of this parasite to man has not yet been achieved, other simian parasites, such as *P malariæ* of chimpanzees and *P hylobati* of gibbons, are also suspected but not proved to be zoonoses *P cynomolgi bastianellii* (as this latest parasite is called) originated from a crab-eating monkey (*Macaca irus*) captured in Pahang, and the next stage of the research will be to discover first how many (if any) of the local inhabitants of this forested region are infected with the parasite, and secondly how widely it is distributed in the East Indies, Thailand, and the Far East With such a monkey reservoir of malaria, eradication may be an even more difficult undertaking than it seems at present, but, until the situation has been investigated fully, the extent of the danger cannot be assessed It may even be found that the parasite does not exist in Nature, but was the result of one of the flagrantly unnatural processes to which the parent strain had been subjected it was originally contaminated in both sexual and asexual forms with *P knowlesi*[13], it was flown across the Atlantic in iced blood, and it was maintained in a variety of exotic mosquitoes very different from its original insect vector

If malaria is to be eradicated from the world, these and other problems will have to be solved Even then the subject of malariology will not be extinguished, because much remains unknown about the malaria of lizards and birds, rats and lemurs, and bats and antelopes, and, though their parasites do not appear to affect man, the zoologist will be impelled to investigate them further, with their attendant insect hosts

The Mongol Chromosome and Some Others

THE spate of new observations on human chromosome anomalies continues, and it seems worth following our recent attempt to survey the X chromosome disorders[1] with a similar account of one of the autosomes

Anomalies of the "mongol" chromosome (no 21 on the Denver system[2]) have been most studied indeed, apart from the sex chromosomes, this is the only one that can yet be associated in any but the most tentative way with a definite clinical syndrome Classical mongolism has now been shown beyond dispute to be caused by an extra chromosome, no 21[3-5] "Caused by", we would repeat though we do not know how the effect is produced, the relation is too strong to shelter behind the circumlocutory hedging implicit in the words "associated with" The production of "trisomy" of this kind, with three apparently normal chromosomes instead of the normal pair, by the process of non-disjunction during formation of the gamete, the effect of age on the incidence of non-disjunction, and the consequent explanation of the influence of maternal age on the incidence of mongolism are now familiar themes Interest is concentrating on certain cases in which the effect of trisomy-21 is produced by something other than the usual mechanism Such cases have been sought where youth of the mother, or (more certainly) evidence of familial transmission, has suggested that the ordinary non-disjunction mechanism has not been at work The first of these was reported by POLANI et al[6] earlier this year A mongol girl, one of a number examined because their mothers were much younger than usual at the time of their birth, was found to have the normal total number of 46 chromosomes One chromosome of the very characteristic medium-sized acrocentric group (nos 13–15, the "wishbones") was missing, and instead there was an atypical larger chromosome Ingeniously and most plausibly, POLANI et al accounted for this by assuming that the patient had a third no 21 present (thus accounting for her mongolism) but that this had fused with the missing no 14 (or thereabouts) to give the abnormal larger chromosome ("Fusion" oversimplifies the process, which is probably one of translocation, with exchange of material between two chromosomes if in this process a large fragment of one chromosome is exchanged for a small fragment of another, the result will be a large chromosome carrying most of the material of both and a small one carrying much less When these are separated in the process of gamete formation, imbalance will clearly result)

More recently PENROSE et al[7] have reported further "translocation" mongols One was much like the first, except that the extra no 21 was apparently joined to no 22 instead of no 14 In addition, they reported a most remarkable family. Two mongol sibs each had 46 chromosomes, with the same 21/15 translocation-fusion to account for it. In addition, three normal female relatives were found to have 45 chromosomes only. In them an essentially normal chromosome complement had apparently been affected by the "fusion" of one chromosome each from the pairs 15 and 21. In this family the translocation had obviously occurred at least in the great-grandparents. The mere joining together of two chromosomes had no recognisable effect, but the tendency to imbalance during gamete formation inseparable from this fusion gave rise to some offspring with too much chromosomal material, who were the mongols. The importance of this form of transmission has been established by the description of a very similar but even larger family group by CARTER et al.[8] The mechanism is fairly easy to follow from the diagram (fig. 4) of POLANI et al.[6]

[7] Penrose L S , Ellis, J R , Delhanty, J D A *ibid* Aug 20, 1960 p 409

Another remarkable family was reported by FRACCARO et al.[9] Here the mongol patient had 46 chromosomes, and an abnormality of the smaller chromosomes which was thought at first to represent the ordinary mongol trisomy of no. 21, with translocatory pseudo-fusion of two of the three to produce an abnormal single larger chromosome. His father, who appeared perfectly normal and is a minister of religion (and who may thus be the first exception to the rule that chromosomal anomalies and university degrees are incompatible) was found to have 47 chromosomes and to be trisomic for no. 19. The findings in this family admit of no simple explanation with our present knowledge, unless indeed (as seems unlikely) the diagnosis of the child as a mongol is at fault. But clearly we must expect some strange findings from the systematic examination of familial mongols. There are rumours of yet other variants on the way.

Anomalies of other chromosomes form a much more confusing picture. Trisomies of no. 17[10] and of one of the 13–15 group[11] seem well established. Trisomy of no. 22 is also not unlikely,[12] though identification of the chromosome present is not very certain (might it even have been an extra Y?) and its relation to the Sturge-Weber syndrome present cannot yet be accepted confidently. Trisomy of no. 11[13] and of no. 6[14] have both been claimed, but both cases had the double sex chromatin characteristic of the XXX syndrome,[15–17] and, as we[1] and others[18] have already suggested for the first of these, these may well both be examples of the XXX syndrome with perhaps minor irregularities of one of the X chromosomes concerned. Multiple trisomies have also been reported,[19][20] the most striking being FRACCARO et al.'s case[21] with 49 chromosomes altogether (nos. 8 and 11 trisomic, plus XXY), and indeed, except for the viability of the patients, there is nothing incredible about this, for the conditions which cause non-disjunction of one chromosome pair could quite reasonably be supposed equally to affect others. Perhaps the most nearly incredible of all the findings is the demonstration by BÖÖK and SANTESSON[22] of trisomy of every chromosome pair, giving a triploid individual with 69 chromosomes.

It is too early to hope to decipher the pattern which must lie behind the varied clinical manifestations of these anomalies. The sex-chromosome disorders present at least some trace of logic, and mongolism, though we have no glimmer of hint as to the mechanism by which the chromosome defect produces its highly specific effects, presents at least a consistent pattern. Of the others hardly any two cases are sufficiently alike for conclusions to be possible. It seems not unlikely that there will be found to be some non-specific tendency to congenital anomalies related more to the amount than to the nature of the chromosomal anomaly (mental defect being the most constant element), and a first task will be the identification, behind this screen, of more specific patterns related to disorders of individual chromosomes.

The demonstration in viable children of triploidy[22] or trisomy of three large chromosomes[21] at one end of the scale, and in normal individuals of trisomy[9] or translocations[7][8] at the other, shows that the human organism is not as sensitive to such changes as was once supposed. Every one of the twelve chromosome pairs of that old friend of the materia medica, *Datura stramonium*,[23] can exist in a trisomic form, and every one has its characteristic phenotype, or, as one calls it in medicine, its characteristic clinical syndrome. Perhaps we will soon recognise equally characteristic syndromes for each of our own twenty-two autosome pairs.

Tumours of the Bladder

IN the past decade the causes, treatment, and prevention of bladder tumours have aroused much interest. Fascinating questions surround the incidence of this disease. Why is it increasing in younger males? Why is it apparently commoner in towns than in the country? Why is it rare in Japan and India? Now that β-naphthylamine is no longer employed in the dye, chemical, or rubber industry, which industries still use carcinogens such as benzidine?

A possible cause of bladder tumours is the excretion in the urine of an abnormal metabolite of tryptophane. Some biochemists believe that this metabolite is hydroxykynurenin, others that it is hydroxyanthranilic acid or an allied compound. These chemicals can be suppressed in at least three ways: by administering pyridoxine, which alters tryptophane metabolism, or by administering saccharolactone, which inhibits enzyme activity in the urine, or by altering the urinary pH Whether it will be possible by chemical means to prevent so-called "recurring" tumours, which may, in fact, be new tumours due to the persistence of a carcinogenic stimulus, depends on whether the mucosal changes are reversible or whether, once the mucosa has been stimulated by a chemical carcinogen, neoplasia is inevitable even if the stimulus is removed Double-blind trials now in hand may provide the answer

In the treatment of the established case one adverse factor that can be attacked is delay Patients often recognise hæmaturia as a symptom of possibly grave significance But this view is not always shared by the patient's doctor, who may treat painless hæmaturia, without associated frequency or pain, as a case of cystitis, and when the bleeding stops the patient and his relatives are lulled into a false sense of security In hospital, too, the possible gravity of the cause of hæmaturia is often not appreciated recently a patient with this symptom was given an appointment to be seen in the outpatient department three months later We accept pain in the right iliac fossa as a matter of urgency Why cannot hæmaturia be given similar priority? In cases of carcinoma of the bladder, when the delay between the onset of hæmaturia and treatment is less than a month the 3-year-survival rate is 70 5%, but when the delay is 6 months the 3-year-survival rate drops to 36 8%[1] Quick and accurate diagnosis is possible, and this is likelier to improve the results than any changes in the techniques of radical surgery or radiotherapy

In the past ten years surgery and radiotherapy have each held sway in turn Nowadays the limitations of surgery and the dangers of excessive radiotherapy are appreciated, the surgeon and radiotherapist work as a team, seeing, treating, and following up each case together This makes for better results—for example, in cases treated surgically in which metastases develop and require irradiation, and in cases treated by radiotherapy in which surgery is needed for resultant complications

Many factors, including the age and general condition of the patient, must be taken into account in treating bladder tumours When the disease is localised and confined to the mucosa the choice lies between intensive diathermy (either cystoscopic or open) or some form of radiation The complications of intracavitary radiation—contracted bladder, mucosal atrophy, and hæmorrhage—have led to its abandonment in such cases until better techniques can be evolved Diathermy—either electrocoagulation or electroresection—is therefore the method of choice The skilled surgeon can deal with even large tumours by this method, but this technique cannot be safely left to a junior For limited tumours infiltrating no farther than the muscle coat interstitial irradiation may be applied Formerly such tumours would have been treated by radon seeds, but nowadays artificially produced radioactive isotopes (gold or tantalum) are used This represents a technical improvement, for radioactive gold grains are smaller, safer, more accurately implanted, and obtainable in various strengths, while tantalum is relatively cheap, has a much longer half-life than gold, and can be kept at hand so that after cystoscopy the bladder can be opened, the tumour excised, and wire implanted at a single operation[2]

The supervoltage radiotherapy beam, directed either from generators, such as a linear accelerator or a Van de Graaf machine, or from artificially produced isotope bombs (telecobalt or telecæsium units), also has a place in treatment This therapy can render a bladder tumour-free, but sometimes it completely fails to affect the tumour Furthermore external radiotherapy in high dosage can produce radiation damage to the pelvic contents, including loops of small intestine These risks, though small, must be weighed against the possibility of cure and the chance of conserving a normally functioning bladder Using a linear accelerator at 8 MeV MORRISON[3] found that with a tumour dose totalling 4500–5500 rads in 4 weeks, 31% of patients had no tumour visible on follow-up cystoscopy There was a better response with the earlier tumours (mucosal tumours disappeared completely in 43%, and a further 19% became appreciably smaller) but the more advanced tumours also regressed in many cases These results show that supervoltage therapy is an extremely potent weapon and should be considered before recourse to radical surgery

Partial cystectomy has tended to fall into disrepute, largely because it has been employed in the wrong type of case MAGRI[4] has found that with single lesions, irrespective of the histological type (80% were solid anaplastic and infiltrating), where a clear margin of at least an inch was obtained there was a 71% 5-year-survival rate Where, however, the line of excision cut through the tumour or its submucous extensions there were no survivors after 5 years Partial cystectomy, though fairly easy, should be undertaken only after careful thought

Radical surgery following radiotherapy is not difficult provided that irradiation has not been applied over too short a time to too large a volume of tissue or in excessive dosage Radical cystectomy involves the removal of all the pelvic contents except the rectum, and also the lymph-nodes along the iliac vessels WALLACE[5] has found that this operation, undertaken after radiotherapy, as the last weapon in the therapeutic armoury, carries a mortality of 21%, but that it can prolong life by 3 or more years in half the cases of mucosal tumours, a third of the cases in which muscle is infiltrated, and a quarter of the cases in which the perivesical fat has been invaded

The treatment of bladder cancer is still far from satisfactory, but much can be done with our present resources to check the disease. It is heartening to know that a subcommittee of the International Union against Cancer has agreed on a provisional method of classifying and reporting cases, similar to that adopted for cancer of the breast.[6] If this recommendation is accepted the analysis of results should be greatly simplified.

POMP AND CIRCUMSTANCE

THE ceremonial ward round has long been a familiar feature of our teaching hospitals. The Chief, surrounded by acolytes and disciples, proceeds in pomp from bed to bed, pausing now and then to correct a point of history, to confirm or deny the physical findings, to discuss the differential diagnosis, or to pontificate on methods of treatment. Ward-clerks and dressers stand around, shifting from foot to aching foot, bored registrars converse in whispers, nurses tiptoe past with bedpans, patients lie glum and silent while the Round drones on.

Is this the best way of teaching "bedside" medicine and surgery? The *Oxford Medical School Gazette*[7] thinks not. In a pungent editorial, entitled "Is Your W.R Really Necessary?", the *Gazette* reminds us that such methods are frequently discourteous and may sometimes harm patients. There the patient lies, sometimes half-naked, a forgotten object while the discussion rages over his bed. He is listening, moreover, with apprehension to the list of alarming investigations proposed for him, to talk of frightful-sounding diseases that he might have, sometimes to obvious differences of opinion about treatment. The more intelligent and educated he is, the worse his ordeal, for the more likely is he to glean from unguarded remarks some of the grimmer truths about his illness and to penetrate the thin veil of medical euphemisms. It is easy to forget that nowadays, thanks to television and other media of mass information, many patients have a smattering of medical terminology and jargon. And even if the Round removes itself a few beds away to discuss prognosis, other patients have ears, and ward gossip spreads. The physical suffering imposed on ward-clerks by the peripatetic ward round is a less serious matter, but they might listen better and learn more if allowed to sit down comfortably.

The *Oxford Medical School Gazette* suggests that all "bedside" teaching should take place in a room adjacent to the ward, with chairs, blackboard, and X-ray screen, into which patients can be brought when needed, or from which the Round can emerge for a brief visit to the bedside. This sensible idea has already been adopted by some teaching hospitals. We commend it to all. Such an arrangement has the additional advantage of ensuring that the formal "round" is recognised as purely for teaching purposes, as it should be, and is not mixed up with the day-to-day management of patients. It is impossible to teach properly on more than a few cases at a time. Practical therapy should be dealt with by the Chief later, when he goes round his beds privately with his junior staff. The traditional royal progress from bed to bed, with a gracious greeting and a few pearls of wisdom dropped at each one, may awe the impressionable but is not the best way either to teach clinical medicine or to cure patients.

NEONATAL RESPIRATORY DISTRESS

RESPIRATORY distress in the premature infant is a common cause of neonatal death. Most of the affected infants have no evidence of congenital malformation or birth injury, hence they should survive if the distress could be prevented, and their recovery should be complete if it were more amenable to treatment. The challenge to obstetricians (for prevention of prematurity is the best means of preventing these deaths) and to pædiatricians is being met, and there is some encouraging progress to report.

In the past, research into respiratory distress has been largely concerned with the pulmonary and circulatory aspects.[1] This has proved less enlightening than was hoped, for the ætiology of pulmonary hyaline membrane remains obscure,[2] and the reported disturbances in the mechanics of breathing do not add greatly to our understanding, nor do they suggest any sound alternatives to present methods of treatment based on the administration of oxygen and nursing the infant in a humid atmosphere.

Interest has turned towards the biochemical changes associated with respiratory distress, and this may well prove a more productive approach. The present position has been well summarised by James.[3] Infants with birth asphyxia or respiratory distress become severely acidotic with hyperkalæmia, hypoglycæmia, and possibly hypocalcæmia. These changes are the expected consequence of anoxia and retention of carbon dioxide. They may well be responsible for death, and treatment with glucose, bicarbonate, and insulin holds out some promise of success.[4]

The maintenance of a stable blood hydrogen-ion concentration (pH) depends on the lungs and on the kidneys, and the newborn baby is unique in both pulmonary and renal function.[5] Some of the peculiarities of this period are now being elucidated. Helen Reardon and her colleagues[6] have reported the results of a technically brilliant investigation into the chemical aspects of the control of respiration in the early newborn period. They sampled blood not only from the umbilical vessels at birth but also from the temporal artery at various periods afterwards. They analysed the blood samples for plasma pH, CO_2 content, protein, O_2 content and capacity, and hæmatocrit. From these measurements the pCO_2, buffer base, and oxygen saturation were calculated. The results showed that the normal full-term infant is born with mild acidosis which is of both metabolic and respiratory origin. This is presumably due to an excess of fixed acids or deficiency of base which is uncompensated by hyperventilation. The rise in pCO_2 (respiratory acidosis) suggests that the birth process not only prevents compensation of the metabolic acidosis but leads to impaired CO_2 elimination. Within an hour of birth the respiratory component disappears owing to the efficacy of pulmonary ventilation, but the metabolic acidosis (decrease in bicarbonate or other buffer anions) tends to increase. There is thus a state of uncompensated metabolic acidosis. During the next few hours ventilation becomes efficient enough to compensate for the metabolic acidosis, and in some infants there is evidence of respiratory alkalosis. Correction of, rather than compensation for, the metabolic acidosis takes place in breast-fed infants from the 4th day but is delayed in premature infants Reardon et al argue that plasma-pH is the main stimulus to respiration because, during the phase of compensating metabolic acidosis, there is still increased respiratory drive in the presence of lowered pCO_2 and plasma-pH

McCance and Widdowson[7] have shown that the kidney of the newborn infant secretes an acid urine at birth and in the first 48 hours of life, the acidity is due not to acid phosphates but to a predominance of ammonium salts and organic acids, and Zweymuller[8] has identified some of these as emanating from the citric-acid cycle Probably, therefore, the newborn infant depends greatly on pulmonary function for the maintenance of acid-base balance, when this function fails the metabolic sequelæ may be catastrophic, and perhaps the biggest change is the hyperkalæmia Whether this hyperkalæmia is due predominantly to renal retention of potassium and excretion of sodium or to the excessive liberation of potassium from within cells is uncertain It seems reasonable, however, to attempt to prevent the extrusion of potassium from the cells by adequate oxygenation and administration of glucose

PRISONS IN 1959

LAST year, as the annual report of the Commissioners of Prisons[9] relates, the numbers of prisoners grew yet again (though it fell in the autumn), and the numbers of prison staff increased in rather higher proportion, although many more are still needed New legislation had a rather greater effect on the prison population than usual, with a drop of civil prisoners from 744 to 265 due to the Attachment of Earnings Order and an extra 63 prostitutes under the Street Offences Act Imprisonments without fine continued to rise (by over 2500 to 28,411 for men) as did receptions of men not under sentence (by 1000 to 45,000) This means, as the commissioners say, that a regrettably large proportion of the effort of local prison staff is diverted from training persons convicted of crime For women this defect is even more evident, for only 47% of those remanded before sentence were given imprisonment, and some 85% of these were imprisoned for not more than six months There is a widespread feeling that some alternative must be found to short prison sentences, and the new Criminal Justice Bill published last week (its terms are summarised on p 1082) may lead to their abolition at least for young offenders The suspended sentence was buried in 1952, and the Advisory Council on the Treatment of Offenders in 1957[10] did nothing to disinter it The Council did, however, approve adult attendance centres and call for wide use of remand on bail for full inquiry between conviction and sentence, believing that the knowledge gained in this way would help magistrates to avoid giving imprisonment Lord Kilmuir[11] offered detention centres as an alternative for under-21s—a group of prisoners which increased enormously in 1959 (by over 700 to 2498) Nevertheless, for men, sentences of under three months and over three years are tending to diminish slightly and intermediate ones to increase

Regarding types of offence, convictions for violence against the person again increased, though this may only reflect changes in public attitude and sentencing policy Gordon Hawkins[12] has described grounds for believing that in the past half-century violent crimes have not increased significantly Sexual offences continued their downward trend, but not those against females Thefts of all kinds again increased, but imprisonment for drunkenness decreased (by about 200 to 3129) Heavy traffic and current anxieties about road deaths were doubtless partly responsible for the great increase in imprisonment under the Highway Acts—at 2627 the total last year was nearly 50% greater than in 1958 The views of Lady Wootton[13] and others are evidently making some impact on her fellow magistrates (Even so, the Royal Automobile Club[14] has pointed out that, while all traffic offences increased by 6 6% in the year, traffic volume went up by 10%) Local prisons, unfortunately, still carry the greatest load, holding about 4 prisoners to every 1 accommodated elsewhere Clearly " show " prisons such as Wakefield tell but a small part of the story

Breaches of discipline and escapes continued to cause concern Birching was ordered 11 times (3 in 1958), and this punishment was confirmed in 2 cases by the Home Secretary (0 in 1958) That 1 of these 2 men committed a second assault shortly afterwards must reinforce the belief that the value of corporal punishment is mainly to assuage the feelings of the staff In the contrary direction, however, the approach towards a " therapeutic community " proceeds The Norwich system of freer association between staff and prisoners continued to expand, and group counselling[15] spread to fourteen more prisons and borstals in the year Even at Dartmoor, this system has had a good reception Evening classes are expanding, but progress towards the realistic full-time work and reward system, so essential in training a man for ordinary life, is still disappointingly slow Nevertheless, an Advisory Council on the Employment of Prisoners has been set up, together with a new post of assistant commissioner (industrial) It is one of the anachronisms of the age that thousands of able-bodied men moulder away in gaols while public works, such as waterways and the decaying relics of the 1939–45 war, lie neglected But at least the pre-release hostel and training scheme is spreading as its success becomes more obvious Another means of reintegrating the offender with society is by home leave, over 300 borstal lads were thus paroled, and only 1 in 30 broke it

Detention centres remain one of the brighter hopes of the commissioners for coping with the " bulge " of moderately delinquent youth, and the new Bill seeks to make wider use of these centres But, despite great shortage of places, unsuitable lads—persistent offenders, the physically or emotionally disturbed, and approved-school failures—are too often sent to these centres, where they are not helped by the brief period of highly disciplined and energetic life, and where their presence has an adverse effect on others A better system of classification or of advice to magistrates is needed Whether this stern type of institution is more effective than milder methods has still to be shown by valid comparative techniques Over 50% of boys discharged in 1956 and 1957 had been reconvicted by 1960, and this does not sound too hopeful Aftercare, as the commissioners sadly note, is not yet compulsory, but the new Bill includes provisions for its extension to those coming out of detention centres

[14] *Times*, Aug 10, 1960

[15] See *Lancet*, 1959, ii, 1015

Physical health in prisons remains good, and the trend towards using outside facilities continues, but the number found insane on remand jumped to almost double despite a decline in the number remanded for mental observation and report It is hard to explain these trends, perhaps the new outlook inherent in the Mental Health Act of 1959 may have permeated the prison medical services more quickly than it has influenced the judicial authorities

The prison services, avowedly therapeutic organisations these days, are under as much obligation as, say, the manufacturers of drugs to assess and to publish their results, particularly where new techniques such as group counselling are introduced In a recent lecture the Home Secretary [16] endorsed the views on research we put forward last year [15] It is therefore disappointing to find so little about new methods in the report In support of group counselling it includes a few staff impressions and a couple of letters from prisoners, only in an appendix is there some worth-while evidence—from a local prison where, despite a rising population, the Norwich system led to a drop in disciplinary reports of 131 to 369, and the continuing lapses were less serious than before Other than this, the cynic might be led to correlate the trend towards easier relationships in and out of the prison with the increase of indiscipline, escapes, and overcrowding which the report mentions A larger chapter on "Research" is needed in this valuable document The Home Office research unit, which is already doing a great deal, should stop hiding its light under a bushel Bricks and mortar may still be badly needed, but knowledge must be given a new priority

HUMORAL AGENT IN MIGRAINE?

BROADLY speaking, the mechanism by which symptoms are produced in an attack of migraine is agreed, but the exact changes in cranial blood-vessels and nearby structures which cause the characteristic head pains are still in dispute

Chapman et al [17] working on the hypothesis that besides local vascular change some inflammatory or pain-producing substance was produced locally, examined tissue-fluid from regions of the head which were tender during a migraine attack Specimens were collected by slowly injecting 2 ml of sterile physiological saline solution into the local subcutaneous tissue and then gently withdrawing some of it Controls were provided by taking samples from the scalps of migraine patients both during attacks and at other times, from people not subject to headache attacks, and from the subcutaneous tissue of the forearms of each subject In the headache subjects a substance was found which bioassay suggested was a polypeptide This substance, for which Chapman et al suggest the name "neurokinin", was present in small quantities in all specimens from all subjects, but very much larger quantities were found in tissue-fluid from the scalp of patients with headaches at the time the specimens were taken It was also found to be released into the segmental cutaneous tissue-fluid during dorsal root stimulation and in the axon flare reaction In one subject the substance was apparently reduced in amount after administration of ergotamine tartrate, and Chapman et al suggest that interference by ergotamine with an enzyme system liberating "neurokinin" from a plasma-globulin may be the basis of this effect

These results are extremely interesting They may possibly explain some of the longer-lasting features of migraine which apparently outlast the aura and headache But bioassay methods can be unreliable, and these findings will need to be confirmed and the substances if possible defined chemically

TUBERCULOSIS IN AFRICA

IN the first of the four Heath Clark lectures, delivered in London on Nov 2, Dr Charles Wilcocks traced the development of investigations into tuberculosis in Africa This disease, he said is still spreading, and drug treatment by itself is unlikely to provide the whole answer

Wide variations in incidence and mortality among different races, noted as long ago as the beginning of the century, had led Cummins to formulate his "virgin soil" theory According to this, primitive tribes were highly susceptible because, in the absence of the bacillus, they had never in their own surroundings been obliged to protect themselves against it, while those living in more urban communities had elaborated protective substances through contact with the bacillus The high tuberculosis incidence and mortality among African troops in Europe in the 1914–18 war seemed to support this theory, though subsequent workers had suggested that the troops involved had been in France for some time and that they broke down under stress in other words, that the cause lay more in the environment than in racial susceptibility

Between the wars extensive work by individuals and commissions, ably supported by administrators, led to an accurate assessment of the distribution and character of the disease It was found to be widely distributed and it progressed rapidly to death, with extensive cavitation and little fibrosis, and usually with involvement of both lungs The sputum was heavily infected, and this was clearly a factor in spread when the patient and the rest of his family slept together in small, poorly ventilated houses

Some idea of the distribution of the disease could be gained from the large proportion—41%—of the total health expenditure of the Union of South Africa devoted to tuberculosis In the mines pneumoconiosis had added to the problem, although more careful selection of recruits and measures to cut down dust had reduced the number affected

Treatment, previously limited to bed rest and an occasional pneumothorax, had been radically changed by the advent of effective drugs But these might fail to control the disease, especially if the patient was not treated in hospital, because many did not take *p*-aminosalicylic acid with their isoniazid, and others stopped treatment before they should Thus resistance developed on a large scale

B C G vaccination was sometimes the only rapidly applicable preventive measure, and its value was probably small But these were short-time measures For widespread improvement, the attitudes of members of very different cultures had to be modified and research undertaken into the means of persuading whole communities to change habits which favoured the development of tuberculosis The most pressing need was improvement in environmental conditions The emphasis had now shifted to stress as the main causal factor in tuberculosis Nutrition, housing, working conditions, and hygiene and sanitation all required attention The £10 million per annum spent by the South African Government in the past five years on housing for non-Europeans was a step in the right direction It was unfortunate that the World Health Organisation, in its last report on the subject, had barely touched on the environmental factor, presumably because it was considered self-evident But anything which was not mentioned tended to be forgotten

It was the doctor's duty to stimulate the administrators to improve conditions, just as had been done in England a century ago

A SEX-LINKED FAMILIAL PURPURA

THE classical sex-linked hereditary bleeding diseases are hæmophilia and its close relation, Christmas disease In the past six years there have been reports of a purpuric hæmorrhagic disorder with a similar mode of inheritance by a sex-linked recessive gene—i e , the condition affects males but is transmitted by female carriers who are unaffected, and each male has an equal chance of being affected or free The condition, first described in 1954 by Aldrich et al ,[1] presents the odd combination of thrombocytopenic purpura, eczema, and undue liability to infection In the family, of Dutch extraction, observed by Aldrich et al , the male infants were known to be liable to die in the first few years of life with " draining ears, eczematoid dermatitis, and bloody diarrhœa ", in the last three generations 16 out of 40 males had died with this disease before the age of 31 months Krivit and Good [2] investigated the same family in 1959 and found that there were 2 female carriers who were reproducing, and that these had had 8 children since 1954, 2 were healthy girls and 6 were boys, of whom 3 had the disease and 3 were healthy

2 cases in an English family have now been reported by Gordon,[3] of Sheffield He points out that seven families affected by the disease have been described, one of them a Negro family Details of 16 male patients are known, and all have died, 1 of Gordon's patients has died, and 1 is still alive

Gordon's 1st patient was admitted to hospital at the age of 14 months with infantile eczema affecting the head, neck, arms, and legs A bleeding tendency had been noted from the age of 4 months, and this had alarmed the mother because she had had a brother who had died of " hæmophilia " at the age of 1 year Investigation showed severe thrombocytopenia, which persisted except for short periods when the count rose above 100,000 per c mm Bone-marrow was found to contain platelet-forming megakaryocytes With treatment the eczema improved, and the patient was sent home He was in hospital again on account of eczema five months later, and at the age of 4 years he was admitted with profuse purpura, bleeding gums, discharging ears, and impetigo The thrombocytopenia being still present, it was decided to carry out splenectomy, and this was followed by a rise of platelets to normal and disappearance of the purpura But in the next twelve months the patient had to be admitted three times—once because he had meningitis due to pneumococcal and staphylococcal infections, once for dental extraction which caused no trouble, and finally in a fatal coma Necropsy showed bilateral adrenal hæmorrhages, there was no evidence of septicæmia, the platelet-count was not recorded

Gordon's 2nd case was the brother of his 1st patient, born eight years later, in between, a healthy girl and a healthy boy had been born This 4th child of the family showed eczema at the age of 3 months, and a month later he was investigated in hospital, he had thrombocytopenia, and furunculosis, pyuria, and bronchitis developed while he was in hospital His white-blood-cell count was normal, and he did not have deficient γ-globulin Treatment with prednisolone and then with corticotrophin produced only a temporary rise in the platelet-count In view of the experience with the elder boy splenectomy was not performed, and the patient has remained reasonably well for three years, still having occasional purpura and occasional attacks of respiratory-tract infection

This syndrome will be easily recognised, though we have no doubt that children with eczema and thrombocytopenic purpura will be seen who do not have the syndrome, the added features of recurrent infection and, above all, a positive family history must also be found The cases so far reported have not been very fully investigated Krivet and Good sought platelet agglutinins but did not find them, marrow punctures have shown the same picture as that of " idiopathic " thrombocytopenic purpura, γ-globulins appear normal But nothing is known about the other blood-clotting factors No attempt seems to have been made to find out whether the condition is linked in any way with systemic lupus erythematosus and similar diseases, in which thrombocytopenic purpura is sometimes an early sign We hope that pædiatricians will look out for cases of Aldrich's syndrome and see whether more can be learnt about its ætiology and possible lines of treatment

CHEMICAL MENINGITIS FOLLOWING SPINAL ANÆSTHESIA

FORMERLY, when measures were not taken to avoid contamination of the subarachnoid space with phenolic disinfectants, chemical meningitis was a recognised sequel of spinal anæsthesia [1] Sterilisation by autoclaving of special packs containing all the equipment, including the ampoules of local anæsthetic, required for this form of anæsthesia is now commonly practised to prevent this complication But autoclaving by itself is inadequate if the syringes and needles have not been previously freed from all traces of disinfectant by cleansing and washing

The dangers of inadequate washing of equipment are well brought out in an account of five patients in whom acute meningitis developed very shortly after spinal anæsthesia for obstetric delivery [2] The cerebrospinal fluid in each case was purulent, with a polymorph leucocytosis These findings, together with pyrexia, suggested bacterial infection of the subarachnoid space, but no organisms could be isolated from the cerebrospinal fluid or from blood samples A review of the procedures used for cleansing spinal anæsthetic equipment in the obstetric department concerned revealed that, whereas the ampoules of local anæsthetic were taken directly from their carton before autoclaving, the syringes used were soaked in a solution of a phenolic disinfectant, washed and rinsed, and finally put in trays ready for autoclaving Clearly this washing was ineffective Fortunately, all five patients recovered without permanent neurological sequelæ Their illnesses illustrate once again the dangers associated with this mode of anæsthesia when insufficient precautions are taken to avoid contamination of the subarachnoid space

Points of View

FUTURE ROLE OF THE FAMILY DOCTOR*

E. MAURICE BACKETT
M.B., B.Sc. Lond., M.R.C.P., F.S.S., D.P.H.
PROFESSOR OF SOCIAL MEDICINE IN THE UNIVERSITY OF ABERDEEN

WITH the changing patterns of disease in Western societies, particularly the emergence of the chronic diseases (heart-disease, cancer, peptic ulcer, bronchitis), of accidents (especially motor-vehicle accidents), and of the multiple effects of radiation as the characteristic and newly important threats to the public health, there has come the possibility of a rather different sort of medical care. This new approach is preventive in attitude (though the borderline between prevention and very early treatment is rapidly becoming meaningless). It is preventive in the sense of using our growing epidemiological knowledge accurately to define vulnerable groups, families, and individuals in our population and of manipulating their personal and social environment to prevent disease. But the differences between the present and future preventive medicine are more important than they seem at first sight. These days (and at long last) most of us accept the necessity for clean milk and the quality control of food, for example, without demur. These controls are, for the most part, satisfyingly impersonal. But just let us try advocating changes in the individual and family dietary customs of the healthy rather than the sick in our practices, or their leisure pursuits, or try to change one of many minor addictions to which we are all prone, and we are in for trouble. That trouble is made subtly worse by a sneaking feeling that we may have no right to meddle in these personal matters anyway, and that our techniques, if we do, are naïve. Yet, if the future general practitioner is to attempt the control of chronic disease in his practice, he has little choice—he *must* meddle, and his meddling must be increasingly personal, for it seems very likely that before long our so-called "new" diseases will offer as much of a threat to life and happiness as did some of the epidemics of the 19th century. And, since many of these diseases have their origins in our changing ways of living, a tolerable amount of interference may help to prevent them.

By "new" diseases I do not mean only novelties but *newly important* diseases which, because of their increasing contribution to our morbidity and mortality, must be counted as new threats. For example, with the decline (but not the defeat) of the infections we can see more clearly the enormity of our chronic-bronchitis problem (25 million man-days lost per year, and thousands of deaths), of our cancer problem (100,000 deaths per year), of heart-disease, and of chronic but not always fatal diseases like diabetes and multiple sclerosis. We see, too, the useless (though fortunately small) waste of fœtal and neonatal life and the few remaining maternal deaths in a new context: the context of a society which, perhaps unlike all previous societies, does not expect illness and early death and which thinks of health and happiness as its right.

* * *

We can summarise the main features of our changing disease patterns in this way. First, the *vulnerable age-groups* are shifting. Young people are seldom ill. In fact the older children and adolescents have virtually disappeared from the doctor's surgery. There is increasing emphasis on the intrauterine child and the neonate, rather than the infant. Then there is the new interest, of course, in the elderly, and above all a growing anxiety about the middle-aged. The *sex ratios*, too, are changing, and the new diseases are increasingly selective of males.

Next, the *type of disease* is changing (and, inevitably, our attitude towards it). For example, infectious disease outbreaks are often spectacular and explosive, cases occur near one another, a hundred or so deaths in a small community has the impact of disaster, while the same number of deaths spread over the whole country—motor-vehicle or coronary deaths, for example—does not carry the same provocative danger signal. Some catastrophe is needed to promote social action.

Next there is the *duration of illness*. Most of our new diseases are chronic slow-moving processes which may take many symptomless years to develop. We are told that the cancer of the lung, for example, may have started fifteen or twenty comparatively healthy years before the first symptom of the disease, and that the men now dying of chronic bronchitis may well be reflecting not only their smoking habits and the air pollution of the cities in which they have lived but also the shorter convalescence enforced on working-class families by the tough economic pressures of the hungry '30s. It is, perhaps, this very long duration of our chronic diseases and of cancer which is doing most to force us to review our methods of medical care.

Finally, we can say that with a few exceptions our new threats to health seem, by their very nature, somewhat less likely to respond to curative medicine than the diseases of the past. However, this point is not a strong one, and, to strengthen the case for a review of our preventive measures, I would say that, thanks to the impeccable epidemiology of people like Doll, Case, and Morris, the prevention of many cancers (and some other chronic diseases) is becoming possible long before the disease itself is fully understood. Thus, in the face of our new diseases, *prevention* acquires a new urgency, and the wise family doctor is being forced increasingly to switch his attention from sick people to the habits and behaviour of healthy people many years before the clinical onset of illness.

* * *

So here, very crudely, is the problem. Most people who feel ill seek medical care and have a rather special relationship with their doctors. Healthy people, on the other hand, are unlikely to be particularly impressed by talk of a disease which *may* come in twenty years' time. Their replies to doctors who seek to change their behaviour, and thus to promote their future health, are polite but negative.

The dilemma is most acute for the family doctor, for it is now becoming technically possible for a large part of his job to be the highly scientific supervision of healthy people. Indeed, this looks like being the only way to cope with our new diseases. Such a statement does not sound particularly surprising, but at the moment well over 90% of the family doctor's work with adults is curative, dealing with established disease. If even a quarter of his work were to be concerned mainly with healthy people, rather than the sick, this would be a revolutionary change—at least as revolutionary as was his assumption of the role of vaccinator and immuniser of children Such a change has been made *necessary* by the changes in our disease pattern, and *possible* by a growing knowledge of the reasons for variation in the vulnerability of different age, sex, and social groups This means that the doctor who really knows how his patients live will be able to define with increasing accuracy who is likely to become ill In fact, he alone—because of his contact with the family—can become the man to observe those aspects of behaviour which we suspect are the precursors of much chronic disease

---

* Abridged from a paper read to the sociological section of the British Association on Sept. 2, 1960. The full text will appear in *Advancement of Science*.

As a help toward the practical application of this change of approach, the doctor now has a growing armoury of screening devices and simple tests by which he can pick the already ill from among the merely vulnerable people in his practice, and so make earlier and ever earlier diagnoses Many of these screening tests are sensitive enough to be used while the patient is still feeling fit—that is before he would normally seek medical care, and long before serious symptoms arise

* * *

These notions may be illustrated briefly by reference to cancer of the uterine cervix Epidemiologically speaking, this cancer is well described A lot is known about what sort of people get it (but, of course, very little about how they get it) Through relatively simple technical advances it is becoming possible to make increasingly early diagnoses of the developing growth We are told that treatment at an early stage is relatively easy and safe, but that the diagnosis must be made before the symptoms and signs develop We are also told that the test is rapidly achieving real accuracy So it is this combination of good epidemiology (which could guide the doctor to where the disease will arise—so that he need not screen all the women in his practice) and this early test which has suddenly given the family doctor the power if not to eradicate the disease then perhaps drastically to reduce it in his practice But, at once we are back with the same problems as before How to persuade apparently healthy women who belong to the vulnerable age, parity, and social group to seek medical care long before they feel ill, how to persuade the doctor to persuade them, and finally, how to fit this approach into a service and a society quite naturally preoccupied with curative medicine

* * *

Tests which can be used for screening apparently healthy populations for all manner of different diseases are rapidly increasing in number and accuracy They are an exciting product of the growing gadgetry of medicine Already it seems probable that more or less accurate and very early diagnoses (that is, long before the patient is conscious of illness) can be made in a variety of chest conditions, a few cardiovascular disorders, some renal diseases, and an assortment of hereditary metabolic upsets, mild diabetes, and at least one cause of blindness

In this way it seems that our new diseases are themselves forcing us into at least the contemplation of a different sort of medical care This medical care may in turn need a rather different sort of doctor to apply it Such a man would have different interests and would need much more time than today's family doctors whose hospital education very properly emphasises curative medicine above all else

There are other difficulties apart from those of time and interest For example, most doctors feel that, at least at first, we should play a passive waiting role the initiative obviously should be with the patient With this in mind most of us would find it very difficult, for example, to write to a lot of healthy adults on our lists inviting them to undergo even the simplest of screening tests It would be even more difficult to go to the length of reorganising our practices so that much of our time was spent in this way

There is yet another problem How could the future family doctor screen the vulnerable people on his list, offer his genetic counsel, advise effectively on diet, exercise, and so on, or even check the blood-pressure and weight of the paunchily middle-aged (if one day it is agreed that these too are useful screening tests) without creating not a healthy practice but a practice of neurotics? We have seen a suggestion of this mass fear of illness following the indiscriminate "check-up" campaigns, the cancer films, and the commercial exploitation of anxiety which has occasionally been a feature of "health education" elsewhere Our small experience of studies over here, and the wider experience of calmly and well run studies of community health (such as that at Framingham in the U S A), suggest that these dangers can be avoided But they remain an important threat, and the prevention of some heart-disease, for example, might save the lives of mentally healthy men at the cost of converting them into cardiac neurotics

* * *

Changes in disease patterns must always have given rise to new social problems our current transition from *the infections to chronic degenerative disease is* obviously no exception The changing role of the general practitioner is among the most intriguing of these problems, and it may be that in future he will have to be prepared to make himself more of a nuisance to his patients But if he does, will they take any notice of him—and why should they anyway?

EAST-WEST SYMPOSIUM ON PATHOGENESIS OF ESSENTIAL HYPERTENSION*

CLIFFORD WILSON
D.M. Oxon., F.R.C.P.
PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON,
DIRECTOR OF THE MEDICAL UNIT, THE LONDON HOSPITAL, E.1

"ALTHOUGH it appears that essential hypertension is a widespread condition and a frequent cause of premature invalidism and death, there is little agreement about its pathogenesis or about the role of various environmental factors in its production. This lack of knowledge prohibits any rational attempt at prevention. It seems desirable, therefore, to discuss the conflicting views and to delineate fields in which future research might possibly be concentrated with profit."

These were the broad terms of reference of a symposium which was held in Prague early in the summer under the joint auspices of the European Region of W.H.O. and the Czechoslovak Cardiological Society. Some 40 workers, engaged in research on various aspects of hypertension, attended, chiefly from the U.S.A., U.S.S.R., and Great Britain, but almost every other country in Europe was represented.

The detailed proceedings of the conference will be published shortly, and these will include an account of individual papers and the variety of opinions expressed in discussion. Nevertheless it seems worth while to record some personal impressions now which it is hoped may give some idea of the positive achievements of the symposium. Research on hypertension has recently received a fresh stimulus from several different directions, and this was reflected in the lively controversy and some new ideas which found expression during the symposium.

One stimulus in Prague was undoubtedly the opportunity of hearing from Russian investigators about their concept of essential hypertension as a specific neurosis, against the experimental background of hypertension induced in animals by nervous or emotional strain. New interest has also been aroused by epidemiological studies on the role of genetic and environmental factors, one outcome of which is the current controversy on whether essential hypertension is a disease entity or a biological variation differing only quantitatively from the normal. Furthermore, the widespread use of hypotensive drugs with a variety of pharmacological effects has not only emphasised the need for a clearer understanding of the fundamental nature of the disorder, but has also produced some new ideas about possible mechanisms in its pathogenesis. In the investigation of these problems, statisticians, physiologists, experimental pathologists, and pharmacologists are becoming increasingly active. The old controversies about humoral and neurogenic mechanisms have been given a new look by the discovery of intriguing relationships between renin and aldosterone, by more critical assessment of the role of catechol amines, and by the researches of neurophysiologists in several countries on the nervous regulation of the circulation. Added to this is a questioning of the old concepts of the hæmodynamic status in hypertension in which circulatory changes were accepted as incidental to a primary increase in peripheral resistance, so that the search for ætiological factors was focused almost exclusively on this restricted part of the vascular system.

The symposium was arranged as a series of discussions on the following topics: definition, diagnosis, and natural history, epidemiology, the role of emotional and environmental factors, neurogenic factors in the control of blood-pressure, hæmodynamic studies in essential hypertension, vessel-wall factors, metabolic factors, including the possible role of pressor amines, the adrenal cortex, and the kidney.

Although there was considerable divergence of opinion on most of the topics discussed, there was a fair amount of agreement on the nature of the problems which need to be tackled. These I have attempted to summarise in the following questions:

(1) In the light of modern knowledge, can we arrive at any more satisfactory definition of essential hypertension than the present one of "elevation of the blood-pressure without apparent cause"?

(2) In view of the more exact methods of diagnosis now available, how large a proportion of cases, masquerading under the diagnosis of essential hypertension, are really due to some local disease—e.g., of the kidneys or endocrine glands?

(3) Is it possible to find a means of separating normal from high blood-pressure, not only in the numerical sense, but also in establishing whether essential hypertension is qualitatively different from the physiological range of the blood-pressure?

(4) How valid are casual blood-pressure readings, especially when used as an index in epidemiological studies? How far can such blood-pressure readings be standardised?

(5) How large a part does heredity play in the pathogenesis of essential hypertension? Is the genetic factor sufficiently large to indicate a primary metabolic fault in blood-pressure regulation as the main cause?

(6) What is the role of environmental factors such as geographical situation, diet (including electrolyte intake), occupation, and particularly, mental strain or emotional stress?

(7) Does the blood-pressure rise with age uniformly in the population as a whole, or is there an excessive rise in a limited group, who as they get older emerge from the normal population owing to the development of a specific disease, essential hypertension?

(8) How often does "transient" or "intermittent" hypertension lead to established hypertension—i.e., is there a definite sequence in the natural history from transient to permanent elevation of the blood-pressure?

(9) Can a prehypertensive state be recognised in which metabolic or vascular responses may make it possible to anticipate the development of essential hypertension?

(10) What part do nervous, renal, and endocrine mechanisms play in determining peripheral vascular resistance? Is there any real evidence that these factors play a different role at different stages of the disease?

(11) Is the regional distribution of increased peripheral resistance the same in all cases? Is it different in the early and late stages, and does it differ from the distribution in other hypertensive disorders such as renal hypertension?

(12) Is it possible that, with advancing age, some alteration in the vessel wall may produce a change in reactivity to physiological stimuli?

For the various topics in the symposium, discussion leaders were appointed, and produced a day-to-day progress report. In the final discussion on "topics and future trends for research arising from previous discussions " an attempt was made to coordinate the results of the conference, particularly with a view to international co-operation in various fields. In what follows, I have tried to give a brief account of the general conclusions on the various topics seriatim, but it must be recognised that on some issues there is still considerable disagreement on both the validity and the interpretation of the available evidence, or on its relevance to essential hypertension.

---

* This article is based on a summary review of the symposium presented to the Czechoslovak Cardiological Society, and a lecture on experimental hypertension to the Czechoslovak Nephrological Society, Prague, June, 1960.

Definition and Natural History

On the question of *definition* it was generally agreed that at present there is no satisfactory alternative to the term essential hypertension, indicating " a common form of high blood-pressure without apparent cause ". Whilst modern diagnostic techniques are revealing increasing numbers of cases due to specific lesions, such as renal-artery stenosis, pyelonephritis, or endocrine disease, this is almost certainly a minority group—not large enough, for example, to invalidate epidemiological studies based on measurements of blood-pressure as the sole criterion. In the individual it is impracticable to define a critical dividing-line between normal blood-pressure and essential hypertension; but this is equally true of other forms of hypertension—e.g., that due to renal disease. Whether essential hypertension is a disease entity, qualitatively different from the physiological range of blood-pressure, may well be decided by a critical analysis of existing epidemiological data, together with further planned investigation of selected populations. If indeed we are dealing with a specific disease, some biochemical fault should eventually be discovered. There is evidence that patients with essential hypertension do show qualitative differences from the normal—for example, rapid electrolyte diuresis following plasma-volume expansion by a water or solute load, reversal of the normal antidiuretic effect of injected angiotensin, and the recent evidence of increased secretion of aldosterone in malignant hypertension—but it has yet to be shown that these differences in behaviour are specific for essential hypertension and that they are primary rather than secondary manifestations.

One of the most urgent needs is a clearer definition of the *natural history* of the disorder. Physiologists, experimental pathologists, and epidemiologists are tending to interpret their various data in terms of the " early " or " late " stages of the disease, but there is as yet no clear understanding of these stages or indeed of the relationship of transient to established hypertension. It may well be that further clarification of the natural history will emerge from characterisation of the various states (if these exist) by biochemical or physiological tests. Thus, response to salt-loading or angiotensin, or differences in secretion, utilisation, or end-organ response of adrenal cortical hormones, may be found to differ in different clinical groups; or again there may be a change in hæmodynamic pattern in terms of cardiac output and distribution of regional resistance. Possibly nervous and humoral factors play different roles in the early and later stages. We know, for example, that a minority of cases, especially in young subjects, have an increased cardiac output. Whether this is due to anxiety at the time of the investigation and whether it can still be demonstrated after hypertension has persisted for many years needs to be determined. Whilst some of these questions—e.g., a better definition of stages of the disease—may be answered by large population studies, most of them will require long-term and more detailed investigation of small numbers of patients by the clinician and experimentalist working together. For, apart from problems of differential diagnosis, it will be essential to recognise the intrusion of secondary factors, such as local atherosclerosis, altered renal function, or emotional reactions, which may modify the physiological pattern and bring into play new homœostatic mechanisms.

Epidemiology

The starting-point of epidemiological studies is the validity of blood-pressure estimation as an index. Examination of the " casual " blood-pressure should be made to see whether further standardisation of technique is possible and what additional criteria can reasonably be included in population studies. The epidemiologist is on uncertain ground until the validity of the high casual pressure as an indication of essential hypertension is assured. But if this can be established, some of the really fundamental problems of ætiology may be solved by epidemiological methods. The most important of these is *heredity*. If the genetic factor in essential hypertension is of major importance there is an urgent need to seek for an inborn error of metabolism in the pathogenesis of the disease. Even if there is a specific genetic factor, the environmental situation may well determine whether this defect leads to manifest disease. Furthermore a distinction (commonly overlooked) must be made between genetic factors and the " cultural inheritance " which is also transmitted in the family. The influence of *age* is the second main problem which epidemiological studies should be able to resolve, for if a substantial rise in blood-pressure can be shown to develop in a discrete section of the population as age advances, in contrast to little or no rise in the remainder, there can be little doubt that essential hypertension exists as a separate entity; furthermore the search for a causal mechanism can then be directed to changes in function with advancing age. There is a good deal of evidence, at present difficult to evaluate, of blood-pressure differences between population groups, which may be related to ways of life. It is in the epidemiological field that international cooperation is likely to be most fruitful, particularly in the investigation of racial factors, the effects of diet, the stresses of industrialisation, and other circumstances where differences in prevalence, already recognised, present " experiments of opportunity ".

The Neurogenic Hypothesis

The view that essential hypertension has a neurogenic basis is undoubtedly enjoying a new wave of popularity. Investigators in the Soviet Union have for some years maintained that essential hypertension develops as a specific manifestation of neurosis, and this has led to observations on the prevalence of hypertension in different occupation groups, to extensive physiological researches on the nervous regulation of the circulation, and to studies in dogs and monkeys of experimental hypertension produced by stress stimuli using conditioned reflexes and Pavlovian techniques. The widespread use of hypotensive drugs which act centrally or peripherally by inhibiting autonomic vasoconstriction has produced in some quarters an uncritical acceptance of the neurogenic theory, or at any rate of an important nervous component in essential hypertension. Supporting evidence has been sought, particularly in the United States, by analysing the emotional and hæmodynamic responses of hypertensive individuals to stressful situations, or by studying cultural background, character structure, and behavioural patterns in relation to the incidence of the disease Owing to lack of translations of published data it is impossible to give a fair assessment of the Russian view, and it is to be hoped that the clinical, experimental, and epidemiological evidence on which this concept is based will soon be made more readily available At present most workers agree that in the established phase of essential hypertension—i e, when the diastolic pressure is persistently raised—there is no convincing evidence that the cause is neurogenic vasoconstriction That emotional stress can cause acute elevation in blood-pressure is undoubtedly true, but the relevance of this to the chronic disorder we term essential hypertension is quite obscure, and in neither transient nor established hypertension has increased autonomic activity been demonstrated by the finding of increased catechol-amine production, as is observed in patients with high blood-pressure due to phæochromocytoma There is obviously a need for a more critical and broadly based assessment of hypertension of supposedly nervous ætiology in terms of its clinical characteristics, hereditary origins, and subsequent course Furthermore when studying emotional responses in both personal behaviour and vascular reactivity, it is essential to establish to what extent these are the cause or the result of the elevated blood-pressure

Hæmodynamic Changes

From what has been said it will be obvious that the largest single obstacle to understanding the genesis of hypertension is an imperfect knowledge of the factors which control the blood-pressure in health It would be easier to decide whether hypertension was " abnormal " if we understood better the mechanisms by which normal blood-pressure is maintained This becomes even more obvious when considering the further problems of hæmodynamic changes, vessel-wall factors, and the possible role of renal and endocrine dysfunction in essential hypertension In the field of blood-pressure regulation, physiologists seem to have been until recently almost exclusively concerned with the autonomic control of vascular tone In various discussions a great deal was heard about the baroceptors and other vascular receptor mechanisms, about cardiovascular changes following hypothalamic stimulation, and about the central and peripheral effects of hypotensive drugs on autonomic status and catechol-amine production It is well established that the response threshold of the baroceptors is raised in chronic hypertension, but this appears to be an adaptation to the high blood-pressure rather than its cause Recent physiological and pharmacological work has certainly revealed new aspects of neurogenic control of the circulation, but those who are concerned with the problem of hypertension, either clinically or experimentally, are questioning the adequacy of this approach, and are seeking information on other possible regulating mechanisms which may be more relevant in maintaining blood-pressure at a high level For example, what controls the residual arteriolar tone when all sympathetic influences are removed? Is it some endocrine factor, a renal pressor substance such as angiotensin, or is it a question of the electrolyte environment of the smooth-muscle cells of the arteriole? Whatever the controlling factors, vessel tone varies under the influence of a number of stimuli, and this brings up the vexed question of vascular reactivity Pressor responses to vasomotor stimuli such as cold, emotion, and vasoconstrictor drugs have so far failed to provide a convincing separation of hypertensive from normotensive subjects or to predict the future development of high blood-pressure in the latter Yet the level of the blood-pressure alone is insufficient to explain individual differences in the production of both functional and structural vascular reactions—e g, hypertensive headache, papillœdema, fibrinoid arteriolar necrosis and localised cerebral vasoconstriction in hypertensive encephalopathy

In general the view has long been accepted that narrowing of the arterioles is the primary hæmodynamic change in essential hypertension An alternative view is that vasoconstriction may occur as a reaction to increased intra-arterial pressure, which might be caused, for example, by a rise in cardiac output This possibility has directed attention to primary changes in cardiac dynamics and to possible alterations in venous tone or venous blood-volume, which might affect cardiac output and thereby initiate arterial hypertension Deviations from normal behaviour, such as the rapid salt diuresis in chronic hypertension, and the link between reduction in plasma-volume and blood-pressure after administration of diuretics such as chlorothiazide, have suggested a disturbance in the relationship between vascular capacity and blood-volume in the hypertensive patient Various new and interesting techniques are being developed in an attempt to explore these possibilities Methods have been devised for a more exact physical analysis of the parameters of vascular tone, and it is hoped that these may provide a means of identifying and assessing the effects of neurogenic and humoral factors, and of vascular " reactivity ", in hypertension of various sorts Hæmodynamic studies on cardiac output, and on the regional distribution of peripheral resistance, suggest that in hypertension certain areas of the vascular bed—e g, the kidneys and skeletal muscle—respond differently in different circumstances Experimental models are also being devised in animals in an attempt to separate the cardiac component from the role of the peripheral circulation during changes in blood-pressure induced by various means

Metabolic Factors

The symposium included a number of papers and a very critical discussion on the role of pressor amines, the adrenal cortex, and renal factors in the pathogenesis of essential hypertension Most workers agreed that at present there is no direct or convincing evidence that either the kidney or the endocrine system plays a part in the early or later stages, although this may not be true in the malignant phase of the disease Here again we are faced with the problem of distinguishing primary factors from secondary changes which develop in severe hypertension as a result of renal vascular damage Such damage may produce metabolic disturbances—for example, in sodium and water excretion—and may possibly alter the pattern of hormone production (e g, hyperaldosteronism in malignant hypertension) Nevertheless recent work on the reciprocal action of renin and aldosterone, and on the relationship of renin production by the juxtaglomerular apparatus to renal perfusion pressure, have produced, if not yet a promise, at any rate a hope, of a clearer understanding of renal participation in blood-pressure regulation

There is another line of approach, based on both clinical

and experimental observations, which is certainly relevant to the problem of chronic hypertension in general, and possibly by analogy to essential hypertension This is the growing evidence of a change in mechanism when high blood-pressure passes from the acute to the chronic stage Thus when hypertension is caused by some specific lesion—e g , phæochromocytoma, adrenal cortical tumour or unilateral renal disease—the pressure frequently remains elevated when the primary cause is removed As far as present evidence goes, it does not seem possible to distinguish this chronic residual hypertension from essential hypertension on clinical, physiological, or anatomical grounds There is some evidence also of a difference in mechanism between the hypertension of acute and chronic nephritis and early and late experimental renal hypertension These observations underline the importance, first, of looking for a similar change in mechanism in the development of essential hypertension, and, second, of considering the possibility of a common factor in the various forms of chronic high blood-pressure The striking thing is that in all these conditions a new equilibrium appears to have been established at a high level of blood-pressure which is consistent with many years of good health This would appear to involve a " resetting " of the homœostatic mechanisms which normally maintain arterial pressure at a steady level There is evidence of such a resetting in the case of the baroceptors, but, as already mentioned, the evidence does not suggest that this is of causal significance One of the most clear-cut observations in this field is the reversibility of chronic renal hypertension In the laboratory animal, renal hypertension of long duration is reversed within a matter of hours if the renal circulation is restored to normal In man a similar prompt reversal of chronic renal hypertension has been demonstrated when, in identical twins, a normal kidney has been grafted in a twin with chronic nephritis and the diseased kidneys removed Thus it is clearly established that, in the maintenance of chronic renal hypertension, no irreversible extrarenal mechanism—structural or neurogenic—supervenes This does not of course exclude the participation of some extrarenal factor, but it does indicate that in this form of chronic hypertension a metabolic renal disturbance almost certainly plays a primary role in resetting the homœostatic regulation of the blood-pressure at a higher level In other forms of chronic hypertension, including essential hypertension, this line of reasoning is effectively blocked by the fact that, at any rate until the late stages, there is no structural basis for a renal mechanism If therefore the kidney plays a role in the pathogenesis of essential hypertension it must be on the basis of a purely functional disorder, or of structural changes which have not been so far revealed by light microscopy This is a main problem for future investigation One of the most urgent needs is a further clarification of the mechanism of renal hypertension, for, from what has been said, this may open the way to an understanding of other forms of chronic high blood-pressure

Views on the pathogenesis of essential hypertension have recently been expressed, on this and other occasions, in which the high blood-pressure is deemed to depend on a variety of influences—genetic, nervous, emotional, dietary, renal, and endocrine—with the corollary that no specific cause is likely to be found in the great majority of cases These " multiple choice " hypotheses, which embrace all the possible mechanisms of blood-pressure variation, fail to distinguish, and indeed seem to discount the need to distinguish, these mechanisms from their provoking causes The modes of production of blood-pressure elevation are undoubtedly manifold and may differ in the wide variety of individuals who present with arterial hypertension But some single factor or limited combination of specific factors may well determine that one person gets " essential hypertension " whilst another does not

Conclusion

From these far-ranging discussions I have attempted to outline recent trends in various lines of research which seem to offer promise for the future The Prague symposium made a valuable contribution by bringing together workers from East and West, and by providing the fullest opportunities for critical discussion of their diverse views It brought to the fore the problems and possibilities of epidemiological research on the subject, and presented fresh evidence and ideas on hæmodynamic factors Perhaps of greatest importance was the large representation from the basic sciences—chemistry, physics, physiology, and pharmacology—for from these disciplines are most likely to come new techniques and methods of inquiry

The programme arrangements of the symposium placed the emphasis on discussion rather than presentation of papers, and this was something of an experiment on which both W H O and the Czechoslovak Cardiological Society are to be congratulated What cannot be omitted is a sincere appreciation of the work and friendliness of our medical colleagues in Prague, whose hospitality was not only generous but very largely personal and spontaneous

---

THE FUTURE OF GENERAL PRACTICE

The future of general practice was considered by Dr Oscar Williams in a presidential address to the Association of Welsh Executive Councils at Llandudno on Oct 28

Dr Williams remarked that it had been said that the general practitioner was dead It was certainly true that, except in residential suburbs and south-coast resorts, applications for practice vacancies had fallen almost catastrophically What was to be done ?

The clock could not be put back no practitioner could now, as he did formerly, cope with all emergencies and problems But the pendulum had swung too far the other way, for today the practitioner was forced to refer a high proportion of his patients to a specialist or a succession of specialists before initiating treatment, and sometimes he might lose all control over his patient's treatment

Inevitably the status of the practitioner (he could now hardly be called family doctor) had suffered—and this at a time when in the higher administrative places opinion was moving away from increased institutional treatment, particularly of mental illness, of the very young and very old, and even for midwifery

Those who served on executive councils should welcome this rethinking, and should determine forthwith to play a more creative part in building a complete domiciliary service—an aim which could be achieved only in cooperation with the public-health, hospital, and social services The general practitioner could then become more of a personal doctor, concerned with the social aspects of disease, able and willing to advise the family on its problems, the children, the aged dependants, and the difficulties when the family had to cope with a mentally ill member

Unfortunately there was at present little incentive to this end The Royal Commission on the Remuneration of

Doctors and Dentists had not supplied the answers its report implied that indifferent work paid. The essential minimum requirements were as follows.

The practitioner should have more time to devote to each patient, and this entailed at once cutting big lists and lowering maxima.

He should be properly housed, with all the ancillary help he needed.

He should work closely with his hospital and other colleagues, and he should in fact be invited to participate actively in the work of the hospital and of local-authority clinics, thus averting the frustrations of overlapping.

He should be allowed far more practical participation in the work of hospitals. Clinical assistantships limited to six months' tenure were not the answer, nor even was the provision wherever possible of general-practitioner beds. A family doctor should be able to graduate into the hospital service, as he could formerly.

Another difficulty, which had been only half faced, was the general practitioner's security, or lack of it. The doctor should have the right, without fear of losing his patient, of advising the patient firmly on the course he should pursue, and not merely prescribe the latest tablet. A change of doctors should not be allowed without adequate grounds. Finally, there should be some recognition of higher standards of work.

PENSION AND BENEFIT INCREASES

The proposed increases in pensions, benefits, and contributions, foreshadowed in the Queen's speech, were announced by Mr John Boyd-Carpenter, Minister of Pensions and National Insurance, on Nov 2. The increases, which will cost an extra £160 million a year, will, subject to parliamentary approval, begin next April.

War Pensions

The basic rate of pension for 100% war disablement will be raised by 12*s* 6*d* a week to 97*s* 6*d*. Pensions for war widows with children, or over forty years of age, will be increased by 10*s* a week to 76*s*, with further increases for their children.

National Insurance Benefits

The standard rates of retirement and widows' pensions and sickness and unemployment benefits will go up to 57*s* 6*d* a week for single people and to 92*s* 6*d* a week for married couples, increases of 7*s* 6*d* and 12*s* 6*d* respectively. The allowance for each dependent child will be increased by 2*s* 6*d* a week, and for a widow's child by 5*s*. Maternity benefits, the guardian's allowance, and the child's special allowance are also being raised.

Industrial Injuries Benefits

Injury benefit, now 85*s* a week, will be increased to 97*s* 6*d* a week as will the pension for 100% disablement. The industrial widow's pension of 56*s* a week will go up to 64*s*.

Contributions

The flat-rate contributions for employees in the graduated scheme will stay at about their present level instead of being reduced from next April. The flat-rate contributions for employees contracted out of the graduated scheme, for the self-employed, and for the non-employed will be increased. The contribution from the taxpayer will also be increased.

National Assistance

The scale rates for National Assistance will be raised by 3*s* 6*d* a week for a single householder and by 5*s* for a married couple, to 53*s* 6*d*. and 90*s* respectively. There will be suitable increases in the other rates, including those for dependants.

Symposium

IMMUNOLOGY IN THE RHEUMATIC DISEASES

The Empire Rheumatism Council held a symposium on Immunology in the Rheumatic Diseases in London on Oct 28, under the joint chairmanship of Dr W S C Copeman and Prof John Squire.

Dr L E Glynn (Taplow) said that immune tolerance was an acquired faculty, but one which could also be lost. He outlined possible ways in which antigen- or antibody-forming cells might be altered with subsequent breakdown or avoidance of tolerance mechanisms.

Dr A. G S Hill (Stoke Mandeville) reviewed the clinical evidence that rheumatoid arthritis was a disordered immune response, and found little to indicate a hypersensitivity response.

Reporting a joint study with Dr I M Roitt, Dr W Hijmans (Leiden), and Dr E J Holborow, Dr Deborah Doniach (London) described results of testing sera from patients with thyroiditis, systemic lupus erythematosus (S.L.E.), and rheumatoid arthritis for the presence of antibodies to thyroid antigens, antinuclear factors, anticytoplasmic factors, and rheumatoid factors. About 10% of Hashimoto patients gave positive antinuclear or anticytoplasmic tests, and the incidence of low-titre anti-thyroglobulin antibodies was increased in S.L.E. patients.

Serum complement was diminished in S.L.E., Dr H A. Ellis (Birmingham) found, and might be increased in early active rheumatoid disease, although it fell later, especially when rheumatoid-factor titres were high.

Dr R. R. A Coombs (Cambridge) described the factor—immunoconglutinin—which appears in the serum of rabbits immunised with bacteria specifically agglutinated with antibody in the presence of complement, or indeed immunised with bacteria alone. This factor, apparently an auto-antibody to complement, can be detected in the serum in many human infections, but is increased also in rheumatoid arthritis.

Dr R. G White (London) described the use of immunofluorescent methods to locate -globulin intracellularly in the plasma-cell series in the medullary tissue of lymph-nodes, and in their germinal centres. He drew attention to the follicular hyperplasia and plasma-cell proliferation found in rheumatoid lymph-nodes.

The significance of the rheumatoid serum factors was discussed by Dr J Ball (Manchester), who said that the rheumatoid macroglobulin factor for rabbit globulin could be detected in about 40% of adults, and in significant titre in 2–5% of Northern Europeans. Positive tests were found (apart from rheumatoid arthritis) in a significant proportion of cases of S.L.E., systemic sclerosis, digital arteritis, and Sjogren's syndrome. About 35% of positive tests in a random sample were associated with clinically detectable disease.

Dr C L Greenbury (Stoke Mandeville) described quantitative experiments using radio-iodine to label rheumatoid factor or antibody, which indicated that the amount of factor removable by repeated absorption from a given serum varied according to the degree of sensitisation of the absorbing red cells.

Dr B Cruickshank (Glasgow) doubted whether -globulin was significant in the ætiology of rheumatoid disease. Only a minority of the plasma-cells in the inflammatory lesions of rheumatoid tissue had been shown to contain either 7S or 19S -globulin. He had found histological changes in synovial tissue in ankylosing spondylitis essentially similar to those in rheumatoid arthritis, but associated neither with serum and experimental observations, which is certainly relevant to the problem of chronic hypertension in general, and possibly by analogy to essential hypertension This is the growing evidence of a change in mechanism when high blood-pressure passes from the acute to the chronic stage Thus when hypertension is caused by some specific lesion—e g , phæochromocytoma, adrenal cortical tumour or unilateral renal disease—the pressure frequently remains elevated when the primary cause is removed As far as present evidence goes, it does not seem possible to distinguish this chronic residual hypertension from essential hypertension on clinical, physiological, or anatomical grounds There is some evidence also of a difference in mechanism between the hypertension of acute and chronic nephritis and early and late experimental renal hypertension These observations underline the importance, first, of looking for a similar change in mechanism in the development of essential hypertension, and, second, of considering the possibility of a common factor in the various forms of chronic high blood-pressure The striking thing is that in all these conditions a new equilibrium appears to have been established at a high level of blood-pressure which is consistent with many years of good health This would appear to involve a “ resetting ” of the homœostatic mechanisms which normally maintain arterial pressure at a steady level There is evidence of such a resetting in the case of the baroceptors, but, as already mentioned, the evidence does not suggest that this is of causal significance One of the most clear-cut observations in this field is the reversibility of chronic renal hypertension In the laboratory animal, renal hypertension of long duration is reversed within a matter of hours if the renal circulation is restored to normal In man a similar prompt reversal of chronic renal hypertension has been demonstrated when, in identical twins, a normal kidney has been grafted in a twin with chronic nephritis and the diseased kidneys removed Thus it is clearly established that, in the maintenance of chronic renal hypertension, no irreversible extrarenal mechanism—structural or neurogenic—supervenes This does not of course exclude the participation of some extrarenal factor, but it does indicate that in this form of chronic hypertension a metabolic renal disturbance almost certainly plays a primary role in resetting the homœostatic regulation of the blood-pressure at a higher level In other forms of chronic hypertension, including essential hypertension, this line of reasoning is effectively blocked by the fact that, at any rate until the late stages, there is no structural basis for a renal mechanism If therefore the kidney plays a role in the pathogenesis of essential hypertension it must be on the basis of a purely functional disorder, or of structural changes which have not been so far revealed by light microscopy This is a main problem for future investigation One of the most urgent needs is a further clarification of the mechanism of renal hypertension, for, from what has been said, this may open the way *to an understanding of other forms of chronic high* blood-pressure

Views on the pathogenesis of essential hypertension have recently been expressed, on this and other occasions, in which the high blood-pressure is deemed to depend on a variety of influences—genetic, nervous, emotional, dietary, renal, and endocrine—with the corollary that no cause is likely to be found in the great majority s These “ multiple choice ” hypotheses, which race all the possible mechanisms of blood-pressure variation, fail to distinguish, and indeed seem to discount the need to distinguish, these mechanisms from their provoking causes The modes of production of blood-pressure elevation are undoubtedly manifold and may differ in the wide variety of individuals who present with arterial hypertension But some single factor or limited combination of specific factors may well determine that one person gets “ essential hypertension ” whilst another does not

Conclusion

From these far-ranging discussions I have attempted to outline recent trends in various lines of research which seem to offer promise for the future The Prague symposium made a valuable contribution by bringing together workers from East and West, and by providing the fullest opportunities for critical discussion of their diverse views It brought to the fore the problems and possibilities of epidemiological research on the subject, and presented fresh evidence and ideas on hæmodynamic factors Perhaps of greatest importance was the large representation from the basic sciences—chemistry, physics, physiology, and pharmacology—for from these disciplines are most likely to come new techniques and methods of inquiry

The programme arrangements of the symposium placed the emphasis on discussion rather than presentation of papers, and this was something of an experiment on which both W H O and the Czechoslovak Cardiological Society are to be congratulated What cannot be omitted is a sincere appreciation of the work and friendliness of our medical colleagues in Prague, whose hospitality was not only generous but very largely personal and spontaneous

---

THE FUTURE OF GENERAL PRACTICE

THE future of general practice was considered by Dr OSCAR WILLIAMS in a presidential address to the Association of Welsh Executive Councils at Llandudno on Oct 28

Dr Williams remarked that it had been said that the general practitioner was dead It was certainly true that, except in residential suburbs and south-coast resorts, applications for practice vacancies had fallen almost catastrophically What was to be done?

The clock could not be put back no practitioner could now, as he did formerly, cope with all emergencies and problems But the pendulum had swung too far the other way, for today the practitioner was forced to refer a high proportion of his patients to a specialist or a succession of specialists before initiating treatment, and sometimes he might lose all control over his patient's treatment

Inevitably the status of the practitioner (he could now hardly be called family doctor) had suffered—and this at a time when in the higher administrative places opinion was moving away from increased institutional treatment, particularly of mental illness, of the very young and very old, and even for midwifery

Those who served on executive councils should welcome this rethinking, and should determine forthwith to play a more creative part in building a complete domiciliary service—an aim which could be achieved only in cooperation with the public-health, hospital, and social services The general practitioner could then become more of a personal doctor, concerned with the social aspects of disease, able and willing to advise the family on its problems, the children, the aged dependants, and the difficulties when the family had to cope with a mentally ill member

Unfortunately there was at present little incentive to this end The Royal Commission on the Remuneration of

Doctors and Dentists had not supplied the answers its report implied that indifferent work paid The essential minimum requirements were as follows

The practitioner should have more time to devote to each patient, and this entailed at once cutting big lists and lowering maxima

He should be properly housed, with all the ancillary help he needed

He should work closely with his hospital and other colleagues, and he should in fact be invited to participate actively in the work of the hospital and of local-authority clinics, thus averting the frustrations of overlapping

He should be allowed far more practical participation in the work of hospitals Clinical assistantships limited to six months' tenure were not the answer, nor even was the provision wherever possible of general-practitioner beds A family doctor should be able to graduate into the hospital service, as he could formerly

Another difficulty, which had been only half faced, was the general practitioner's security, or lack of it The doctor should have the right, without fear of losing his patient, of advising the patient firmly on the course he should pursue, and not merely prescribe the latest tablet A change of doctors should not be allowed without adequate grounds Finally, there should be some recognition of higher standards of work

---

PENSION AND BENEFIT INCREASES

THE proposed increases in pensions, benefits, and contributions, foreshadowed in the Queen's speech, were announced by Mr John Boyd-Carpenter, Minister of Pensions and National Insurance, on Nov 2 The increases, which will cost an extra £160 million a year, will, subject to parliamentary approval, begin next April

War Pensions

The basic rate of pension for 100% war disablement will be raised by 12*s* 6*d* a week to 97*s* 6*d* Pensions for war widows with children, or over forty years of age, will be increased by 10*s* a week to 76*s*, with further increases for their children

National Insurance Benefits

The standard rates of retirement and widows pensions and sickness and unemployment benefits will go up to 57*s* 6*d* a week for single people and to 92*s* 6*d* a week for married couples, increases of 7*s* 6*d* and 12*s* 6*d* respectively The allowance for each dependent child will be increased by 2*s* 6*d* a week, and for a widow s child by 5*s* Maternity benefits, the guardian s allowance, and the child's special allowance are also being raised

Industrial Injuries Benefits

Injury benefit, now 85*s* a week, will be increased to 97*s* 6*d* a week, as will the pension for 100% disablement The industrial widow's pension of 56*s* a week will go up to 64*s*

Contributions

The flat-rate contributions for employees in the graduated scheme will stay at about their present level instead of being reduced from next April The flat-rate contributions for employees contracted out of the graduated scheme, for the self-employed, and for the non-employed will be increased The contribution from the taxpayer will also be increased

National Assistance

The scale rates for National Assistance will be raised by 3*s* 6*d* a week for a single householder and by 5*s* for a married couple, to 53*s* 6*d* and 90*s* respectively There will be suitable increases in the other rates, including those for dependants

Symposium

IMMUNOLOGY IN THE RHEUMATIC DISEASES

THE Empire Rheumatism Council held a symposium on Immunology in the Rheumatic Diseases in London on Oct 28, under the joint chairmanship of Dr W S C COPEMAN and Prof JOHN SQUIRE

Dr L E GLYNN (Taplow) said that immune tolerance was an acquired faculty, but one which could also be lost He outlined possible ways in which antigen- or antibody-forming cells might be altered with subsequent breakdown or avoidance of tolerance mechanisms

Dr A G S HILL (Stoke Mandeville) reviewed the clinical evidence that rheumatoid arthritis was a disordered immune response, and found little to indicate a hypersensitivity response

Reporting a joint study with Dr I M ROITT, Dr W HIJMANS (Leiden), and Dr E J HOLBOROW, Dr DEBORAH DONIACH (London) described results of testing sera from patients with thyroiditis, systemic lupus erythematosus (S L E), and rheumatoid arthritis for the presence of antibodies to thyroid antigens, antinuclear factors, anticytoplasmic factors, and rheumatoid factors About 10% of Hashimoto patients gave positive antinuclear or anticytoplasmic tests, and the incidence of low-titre anti-thyroglobulin antibodies was increased in S L E patients

Serum complement was diminished in S L E, Dr H A ELLIS (Birmingham) found, and might be increased in early active rheumatoid disease, although it fell later, especially when rheumatoid-factor titres were high

Dr R R A COOMBS (Cambridge) described the factor—immunoconglutinin—which appears in the serum of rabbits immunised with bacteria specifically agglutinated with antibody in the presence of complement, or indeed immunised with bacteria alone This factor, apparently an auto-antibody to complement, can be detected in the serum in many human infections, but is increased also in rheumatoid arthritis

Dr R G WHITE (London) described the use of immunofluorescent methods to locate γ-globulin intracellularly in the plasma-cell series in the medullary tissue of lymph-nodes, and in their germinal centres He drew attention to the follicular hyperplasia and plasma-cell proliferation found in rheumatoid lymph-nodes

The significance of the rheumatoid serum factors was discussed by Dr J BALL (Manchester), who said that the rheumatoid macroglobulin factor for rabbit globulin could be detected in about 40% of adults, and in significant titre in 2–5% of Northern Europeans Positive tests were found (apart from rheumatoid arthritis) in a significant proportion of cases of S L E, systemic sclerosis, digital arteritis, and Sjogren's syndrome About 35% of positive tests in a random sample were associated with clinically detectable disease

Dr C L GREENBURY (Stoke Mandeville) described quantitative experiments using radio-iodine to label rheumatoid factor or antibody, which indicated that the amount of factor removable by repeated absorption from a given serum varied according to the degree of sensitisation of the absorbing red cells

Dr B CRUIKSHANK (Glasgow) doubted whether -globulin was significant in the ætiology of rheumatoid disease Only a minority of the plasma-cells in the inflammatory lesions of rheumatoid tissue had been shown to contain either 7S or 19S γ-globulin He had found histological changes in synovial tissue in ankylosing spondylitis essentially similar to those in rheumatoid arthritis, but associated neither with serum rheumatoid factor nor with increased serum-γ-globulin In agammaglobulinæmic rheumatoid disease, too, plasma-cells were virtually absent from the inflammatory lesions

Dr J N **McCormick** (Stoke Mandeville) had used partially denatured human γ-globulin labelled with fluorescein to detect rheumatoid factor in unfixed frozen biopsy material from rheumatoid arthritis The cells containing the factor were mainly plasma-cells, and were most numerous in rheumatoid synovial tissue The globulin of the germinal centres, although abundant, appeared to contain very little rheumatoid factor

Fluorescence methods of locating tissue antigens (using fluorescein and rhodamine conjugates) were also described by Dr G **Scott** (Stoke Mandeville) Using anti-glomerulus and antisynovial-membrane conjugates, he had defined three components of human connective tissue by immunohistochemical staining

Dr W R M **Alexander** (Edinburgh) had found that synovial fluid from rheumatoid-arthritis patients injected intradermally in other patients or controls, often gave rise to a delayed skin reaction, apparently of the Mantoux type The active factor, a γ-globulin, was very unstable, and usually did not cause a reaction in the donor's own skin

Discussing his experience with antinuclear serum factor as revealed by the fluorescent-antibody method, Dr D M **Weir** (Taplow) said that the factor was almost invariably present in S L E, but was also found in rheumatoid arthritis, discoid lupus, and some other related conditions, although much less frequently and usually in lower titre He described laboratory investigations on the nature of the antigen(s) reacting with the serum factor

Dr G J **Friou** (Yale) had studied antinuclear factor using fluorescent and radioactive labelled antihuman globulin with whole nuclei, and nucleoprotein, as antigens

Dr W **Hijmans** (Leiden) regarded the L E cell factor as an antibody against nuclear material, and described quantitative precipitin studies between desoxyribosenucleic acid and serum, and complement-fixation studies with histone He gave reasons for not considering the serum factor as pathogenic

Dr E J **Holborow** (Taplow) considered the antigenic possibilities of the polysaccharides of connective tissue He outlined natural and experimental methods of enhancing antigenicity of polysaccharides and drew attention to the lack of knowledge of whether they could take part in hypersensitivity reactions

---

Medicine and the Law

The New Criminal Justice Bill

This Bill deals mainly with offenders under 21 Its main objects are to make wider provision for the use of borstal training and of detention centres in dealing with young offenders, to discontinue short sentences of imprisonment as more detention centres become available, and to extend the provision of compulsory aftercare Changes are also proposed in the law relating to approved schools

Part I remodels the custodial forms of treatment for young offenders No new forms of treatment are proposed, but existing methods, particularly borstal training and detention centres, are extended to more offenders Imprisonment will eventually be restricted to cases where no other sentence is appropriate The new scheme depends on the provision of more borstals and more detention centres, and will be introduced by stages as the additional institutions are ready

Borstal Training

The minimum age for a sentence of borstal training is lowered from 16 to 15 and the court will be able to pass such a sentence whenever they think it expedient that the offender should be detained for training for not less than six months But if an offender is under 17, the court, before passing a borstal sentence, must decide that no other method of dealing with him is appropriate The maximum term of borstal training is reduced from three years to two years and the minimum term from nine months to six months

Imprisonment

The imprisonment of young offenders is restricted to sentences of not more than six months or long sentences of three years or more (except for some offenders who have already been in prison or a borstal) Short sentences of imprisonment are to be abolished by stages as more detention centres become available Imprisonment of offenders under 17 is abolished, but the power of the higher courts to sentence children and young persons found guilty of grave crimes to detention as the Secretary of State may direct is extended At present, this power is confined to offences of attempted murder, manslaughter, or wounding with intent to do grievous bodily harm The Bill extends it to include any offence for which an adult could receive a sentence of 14 years' imprisonment or more

Detention Centres

Where the court decides that a short period of training is appropriate, the offender will be committed to a detention centre For offenders until 17 dealt with by a magistrates' court, the period of detention will be a standard term of three months The higher courts will have discretion to fix the period of detention within a minimum of three months and a maximum of six

Approved Schools

The law about committal to an approved school is not altered, but the Bill provides that a boy or girl of not less than 15 can be removed temporarily from an approved school on a justice's warrant, if this is necessary to maintain discipline, to another approved school, a remand centre, or a remand home for up to twenty-eight days Offenders who turn out to be unsuitable for approved-school training, but are likely to benefit from borstal training may, with the consent of the Secretary of State, be brought before a magistrates' court, which will have power to order their transfer to borstal

Attendance Centres

The minimum age at which a child may be ordered to attend at an attendance centre is reduced from 12 years to 10

Fines

New and, in general, higher limits are set to the fines that magistrates' courts may impose in respect of offences committed by children and young persons, and the obligation on a parent to pay damages of costs awarded against his child is extended to the payment of compensation for loss Enforcement of fines will be by committal to a detention centre or a remand home for offenders under 17

Compulsory Aftercare

This is usually undertaken by probation officers It is extended for the first time to all offenders who are released from a detention centre (unless they were sent there for a default) and to some categories of people released from prison The extension of compulsory aftercare to ex-prisoners will be introduced by stages When it is completed it will include all sentences of four years or more whatever the age of the offender, all sentences of six months or more where the offender was under 26 at the start of the sentence, and all sentences of six months or more when the person has previously had a prison sentence of three months or more or a borstal sentence

In England Now

A Running Commentary by Peripatetic Correspondents

ONCE again the Director-General's Exercise—this year named White Swan—gave us a programme packed with interest, a shop-window of ideas for the future. Some will be discarded, but others will bear fruit I asked three very senior officers what was the biggest problem facing the Army Medical Services today One said the acquisition of broader professional experience. Another said the recruitment of other ranks (and gave me an entertaining lecturette on how to do it) The third said transport, transport, and transport again If you can transport the sick and wounded, quickly and shocklessly, over long distances to the medical centres, you can economise in medical manpower and equipment—and that appeals both to the operational commander, who wants to slim his administrative tail, and to the manpower planner, faced with a return to voluntary service after twenty years of conscription Transport today and tomorrow means air transport (the day after tomorrow it may mean hovercraft or rockets) and the D G duly showed us long-range aircraft, the rotodyne, helicopters—the lot. A French general told us about the enormous use made of helicopters by the French army in Algeria The six-year-old Algerian war has given the French more experience than any other nation of air evacuation, but he indicated that the French Army did not want to go on accumulating this experience.

We also saw the latest types of civil ambulance cars, some with bodies completely constructed of plastic reinforced with glass-fibre, which is strong, light, rustless, and never needs painting Yet with road congestion getting worse every day, will not the local health authorities have to invest in helicopters? Let the R.A.M.C. show the way At the Cambridge Hospital they could establish an accident centre, equipped with helicopters and aerial cameras, to serve the whole of the Aldershot district. The casualty department would be staffed with surgeons of the requisite experience, a helicopter-ambulance could be at the scene of an accident in a matter of minutes (even on bank holidays), and every accident could be photographed from the air What a contribution such a unit could make to research into the causation, prevention, and treatment of road accidents!

An excellent curry—made with dehydrated ingredients and served in a hangar—revived our spirits after the cold of the airfield. We saw the impressive efforts which are being made to modernise and improve military medical equipment The Plastic Age is dawning, and the reductions in total weight and bulk are nothing short of dramatic The new lightweight medical panniers were demonstrated by an extremely smart Nigerian private who has won the Duke of Edinburgh's gold award

I am not yet convinced of the value of the universal container—a lightweight room that can be carried by air and deposited on any little flat piece of ground We saw it being used as an operating-theatre, as a pathology laboratory, as an advanced medical store, as a heatstroke centre, and as the examination and treatment room for a 10-bed medical reception station Perhaps it was the sight of ten "patients" lying in bed in the pouring rain (were there not enough canvas roofs to go round?) that made me feel that further experiment in the design of tentage and supports is what is really needed. The School of Health gave us an admirably straightforward demonstration of ten basic health routines for the soldier, after which there was a bit of a barney about urine tests for paludrine.

The Exercise gets more like an international congress every year None of the American officers would hazard a guess on the result of the Presidential election Eminent officers from the Indian subcontinent spoke to me gloomily about the changed status of their 2000-year-old Maginot Line of the Himalayas A Canadian officer told me that the integration of the Canadian Forces medical branches (which so bewitched our political mentors in the Select Committee on Estimates) had scarcely changed anything Just at present, integration seems to be more urgently needed in certain political circles than anywhere else. At the Exercise supper a well-known authority on malaria prevention presided with patriarchal dignity over a table of pretty nursing officers, and somebody round the piano sang "I'm Dreaming of a White Swansong"

* * *

I am, I confess, a secret thinker, and one day in the rush-hour I caught myself at it again. Suppose a Neptunian scientist (people on Neptune are very large) knowing nothing about life on Earth were to hover over some of our greater cities, studying the traffic. He would notice that the multicoloured shining particles which moved in certain natural channels appeared to obey certain laws These laws, it is true, would not always be rigidly followed, they would be approximate, statistical, stochastic laws, similar to those of chemical kinetics and thermodynamics in our own scientific culture. He would observe, for example, that when a space appeared among a stream of particles, one of them would inevitably sooner or later move into the gap, so that the place left behind it could in turn be filled by another particle and so on, giving the overall effect of a sluggish wave-like forward motion. He might well postulate some kind of force, tending to move the particles by mutual pressure into regions of low population density "Nature", he might aphoristically say to himself, "abhors a vacuum." Or he might notice that when the population-density was high, the noise-level also tended to be high, or there might be a relation between the average rate of the forward wave-motion and the density, or between the noise-level and the mean distance travelled without collision. In short, our Neptunian might soon build up a set of traffic laws akin to the gas laws of physics

At this point in my meditations I stopped my forward wave-motion with something of a jolt, causing a transient sharp rise in the local noise-level. If a Neptunian were to look on us like that, would he be doing anything fundamentally different from what we do when we study the molecules of a gas? And would it ever occur to him that each one of those curious shiny particles, with their semi-random, semi-determinate motions, might contain a living, sentient, meditative being such as myself? Well, then, how about the gas molecules? Who might there not be inside them, I asked myself And, do you know, the thought has bothered me since After all, how do we know that an atom doesn't think of itself as ME? It's time somebody looked into the matter, in my opinion, because if we go on treating the atoms the way we do now, some day there'll be trouble.

* * *

We had a rotten trip back fom the States Even the official log of the *Mauretania* described the conditions as "strong N'ly gale, very rough sea, very heavy N'ly swell" After long deferment of hope in successive arrivals at Cobh and Le Havre, we reached Southampton I telephoned my wife and arranged for her to meet me in Newcastle at 7 A.M The boat train took me to London, where I boarded the sleeper at King's Cross

I woke up at 6 A.M., and reflected that this was the ninth day since leaving New York, but that I would be home in an hour The attendant brought tea I remarked that it seemed very quiet outside. "Yes, Sir," he said, "I'm afraid we're still in Northallerton, and we're an hour behind time. I'm just going to find out what's the matter" He was back in a few minutes to say "It seems, Sir, that the fire went out. They're busy trying to get it going again."

Not even the rich new expletives that I had learnt in America were of any use to me I was speechless

* * *

Our quiet, shy, third-year medical student disappeared behind the screens to examine a middle-aged blonde patient All was well for a few minutes as his examination proceeded, but suddenly the quiet of the ward was shattered by scream upon scream and the words "I wouldn't even let my husband do that." The student emerged blushing furiously to explain to

Sister, who advanced in a menacing way, that he had only been eliciting the patient's plantar responses

* * *

A long time ago I made the mistake of learning how to use a desk calculating machine It was useful to me at the time, because I do not like doing sums and it was much nicer to have a thing like a typewriter to do them for me But it got me a reputation which did me no good at all, and I became known as the department's statistician (unpaid and quite extra to my proper jobs) and general calculator-man I have never been strongminded enough either to repudiate the status or to insist on people learning to do sums for themselves Now, to put the seal on my position, I have been sent on a computer course because " it might be useful if you get the know-how "

I must say the computer people were very nice and friendly to us (I could be friendly too, if someone wanted to learn from me how to use my little desk machine instead of wanting it done for him) Their machine was friendly too, a bit dour the first time we called on him, but then he was said to have a pain in his inside, and an appreciable smell of beer in his neighbourhood suggested that he knew how to look after himself when out of sorts Later he was in splendid form, inverting a large matrix and playing a happy tune on his hooter to announce progress after each thousandth sum or so—i e , a brisk toodleoodleoo, with a thousand to each " ooo " Our job, it appeared, was to learn a language which he could understand well enough to translate into his own dialect, and presently we were writing

```
A = 2
B = 2
A = AB
PRINT (A)
```

which seemed a funny way of putting 2 × 2 and downright wrong algebra But presently we grasped bits of it, and were happily composing letters to the supermachine and even typing them ourselves on the teleprinter which makes the only kind of signs he is really interested in reading

By the end of the course the real mathematicians had become obvious, while some amateurs had fallen by the wayside altogether This was not quite my fate, but I did get a bit mixed up about what was computer-work and what was not I wandered into the unit's common room and was interested to find *The Times* with the crossword only half done The supermachine couldn't have been too slow to finish, it was nice to think that in some ways he might have been too stupid But then computers are apt to have a streak of stupidity look at me still doing the department's sums for them I never thought that this course would show me that what I have most in common with supermachines is a willing nature

* * *

Aunt Pash must be one of my oldest patients She is said to be 93, has one eye, and a colostomy She lost her eye in " one of they girlish pranks " I am not sure what she means by that, but knowing Aunt Pash, I fear the worst I usually visit her hut on the beach when I am in that part of the district, but three times lately it has been empty, and neighbours told me that Pash was visiting However, the last time I was up the Bay, she was home again, and her hut was, as ever, chaotic with spinning and quilting This time there were no tales of her girlhood—the more lurid of which always ended with 'Ah, my dear, the tales I could tell'ee, the tales I could tell ee " No, she had been out gallivanting, and mightily she had enjoyed herself A distant cousin had moved house, and she had gone to help Now it may not be remarkable for an elderly lady to hold very small pieces of china at a housemoving, but in Newfoundland housemoving literally means housemoving The house is taken from its foundation, hauled down to the edge of the water, floated on to a raft, and towed to its new site Once there it is dragged out and hauled into position It is a backbreaking job, and all hands are needed on the lines This is what Aunt Pash had been doing on her holiday Later I was told that she had worked as hard as anyone and cussed better than most I don t doubt it at all

Letters to the Editor

FUTURE ORGANISATION OF PATHOLOGISTS

SIR,—Since with the approach of voting-day for pathologists, past-presidents of the Association of Clinical Pathologists have written to press the advantages of the recent " offer " of the Royal College of Physicians, I write to point to one important fact and event in the history of the Association that has been omitted from recent discussion and documents

The Association of Clinical Pathologists became incorporated on Feb 12, 1956 This was the culmination of the labours of a devoted secretary and had been pursued with enthusiasm by presidents, officers, and council, and the members and all knew that this was the initial stage in the formation of a new and independent college

What is it, therefore, that has caused presidents, officers, and council now so eagerly to favour " the present generous and unequivocal terms " of the recent offer of the Royal College of Physicians ?

That a diploma of membership of a division or faculty of a Royal college would be an almost immediate result of acceptance of the offer is certain, and this would meet one of the needs of pathologists without any great effort—merely the subscription of foundation membership, or examination and membership fees But the status that this diploma might confer would be somewhat reduced by the inferiority attaching to a division or faculty (That a faculty is regarded as inferior is witnessed by the current action of a most ancient medical faculty that seeks by legislation to alter its title to Royal College of Physicians and Surgeons of Glasgow) Surely, the seniors in the Association are not unaware of this implication of inferiority which is not disguised by the use of the term division Why is it therefore that they advise a " short-cut " when the Association has progressed to incorporation unaided ? Everyone knows that a new and independent college may require a few years to have its diploma of membership recognised, everyone knows that a new college is not founded and nurtured without great effort and equally great sacrifice Those who earnestly and sincerely consider that an independent college should be the heritage of our registrars, and in turn their registrars, would work willingly and make sacrifices Is it that in the remaining years of their working lifetime the seniors would rather they held high office and examinership in a subsidiary faculty (of which they are fellows through being fellows of the parent college) than be concerned with great efforts the fruits of which would be enjoyed by posterity and not by themselves ? Or, to put it at a higher level, is it that the senior pathologists who are fellows of the Royal College of Physicians are using their influence to secure to this college, at the time of rebuilding, and for a long time, revenue from the pathologists that in the first instance might amount to around £25,000 ?

London, N 18 J F HEGGIE

SIR,—Dr Joan Taylor and Professor Pulvertaft are two of my oldest friends, but I am bound to tell them that most of their letter of Nov 5 is rubbish

Professor Pulvertaft has had much experience in the appointment of pathologists Has he ever found the absence of a specific higher qualification a handicap ? And if so, how often ? (In this debate a few quantitative statements will be refreshing) He makes appointments, as everyone else does, on the confidential advice of his colleagues and on his own judgment If he has made an occasional mistake I have little doubt that it has been when the flutterings of his warm heart have silenced the warnings of his cool head In our lifetime it has been characteristic of pathology—more, I think, than of any other branch of medicine—that it has drawn its adepts from a wide variety of sources the preclinical sciences, public health, and general practice have all contributed colleagues whom we respect There have been those pathologists who combined the humblest medical qualifications with fellowship of the Royal Society It is one of the weaknesses of the N H S that it is more difficult than it was to change from one specialised branch to another To add any degree or diploma which makes the entry into pathology more difficult or more rigid can only impoverish the science

"Academic centre" is, I suppose, looking-glass language for a college or faculty The adjective is an unusual one to apply to any existing body of this kind except, perhaps, the Royal College of Surgeons As for "a body to speak for pathologists", things have come to a pretty pass if Dr Taylor and Professor Pulvertaft are no longer able to speak for themselves To whom is this body to speak and about what? And who on earth would be able to speak for such a disorderly mob of individualists as we are?

In all this interminable debate the talk has always been of examinations and diplomas but seldom of training Is it not time that we abandoned this babu attitude? The Doctor and the Professor and I all learned pathology in the bad old way, picking up knowledge and experience as we could, piecemeal and without a plan The example of the course for the diploma in bacteriology has shown that a more systematic training is not only possible but desirable I see no reason why the same methods should not be applied to other branches of pathology if some university will give them a trial

Hoccombe, Somerset J A BOYCOTT

SIR,—For Dr Joan Taylor and Professor Pulvertaft I have the greatest admiration and respect, but their idea of an academic centre for pathology in London seems completely out of touch with the ideas of those of us who work some distance from London

The higher qualification and the body to speak for pathologists can be achieved at a very small cost Dr O'Gorman (Nov 5) is rightly daunted by the cost of a building, but what pathologist outside London is going to use such a building?

For meetings, the Pathological Society and the Association of Clinical Pathologists have been able to enjoy the hospitality of numerous bodies all over the country The College of Pathologists could do likewise

Why should not the College of Pathologists start in a small way like the Royal College of Obstetricians and Gynæcologists?

As for withdrawing, as Dr O'Gorman suggests once we are in the Royal College of Physicians it will be impossible to withdraw from that body without its permission The constitution of that body is authoritarian, and it would be unreasonable to expect permission to withdraw to be granted, as G G implies (Nov 5, p 1025)

No, Sir! The only solution appears to be the logical conclusion of Peter Davey's argument He says that the physicians are notable Greek scholars They therefore know that a pathologist is a man who studies disease Their work is therefore pathology, not physic, which is the study of Nature

Let them show their greatness by changing their name to the Royal College of Pathologists We will then join in with them, so possibly will the other Royal Colleges! (Or am I optimistic?) We shall then have a body able to speak for the whole of Medicine

The alternative more likely to be acceptable is for the pathologists to have their own College, and for all the medical colleges, faculties, associations, and societies to join together to form an Academy of Medicine for that purpose

Mumbles, Swansea H C M WALTON

SIR,—As an ordinary pathologist of a very peripheral hospital, may I support the plea of Dr Joan Taylor and Professor Pulvertaft for a vote in favour of the division of pathology within the Royal College of Physicians I started this year firmly in favour of an independent college and, because of the accident that it was my turn to be branch president, found myself defending this view on behalf of the North of England branch at a special meeting of the council of the Association of Clinical Pathologists held in February Because of this I subsequently had quite a long exchange of views with various members of the council, and have since become convinced that a division within the Royal College of Physicians will meet our needs

In the Widdicombe File, G G discusses the various obstacles in the way of an independent college and shows how they might be overcome, but he does not mention the greatest obstacle of all This is that the great majority of the leaders of our specialty do not favour the establishment of an independent college at the present time, but, in all sincerity, prefer the R C P solution It seems to me that it is possible and right for the main body politic of the Association of Clinical Pathologists to stop—if it so wishes—its leaders from going a certain way, but more than this is not possible The real issue in the forthcoming poll therefore is not between the R C P and an independent college but between the R C P and nothing at all for many years to come With the Royal Commission finished, the next ten years may be all-important in shaping the future pattern of British medicine, and it will be bad for both medicine and ourselves if during this time we alone among the major specialties have no official organisation

Northallerton P N COLEMAN

SIR,—Discussions on the future of clinical pathology have assumed that it has a future in the form we know today The supporters of a College of Clinical Pathologists ought to discuss this assumption and have not done so, association with the Royal College of Physicians involves considerably less mortgage of the future

We are not endowed with the gift of prophecy Twenty-five years ago few would have envisaged the position that clinical pathology enjoys today To assume that the present pattern will exist unchanged in 1985 is to make an improbable assumption Two branches (hæmatology and chemical pathology) are growing rapidly and show signs of passing out of the ken both of the general physician and of the clinical pathologist Hæmatology is already well on the way to becoming a subspecialty of internal medicine More slowly, chemical pathology is going the same way, the advent of automation, lessening as it must preoccupation with technique, will accentuate this trend Of the other branches of clinical pathology, hospital bacteriology is being divided more and more between the specialists in hygiene and therapeutics Remains pathology proper, the practitioners of which have always had a well-defined subject which does not take them to the bedside nor make them primarily technicians, it is probably the branch of pathology destined to change the least It seems at least unlikely that most of the subject-matters of clinical pathology will remain in the hands of a group called clinical pathologists and a College of Clinical Pathologists, if established, could become another South Sea House and an obstacle to progress

For reasons set out by Dr Joan Taylor and Professor Pulvertaft present action is needed such action should leave the future uncommitted as far as possible Association with the Royal College of Physicians is the only logical course

Sheffield ARTHUR JORDAN

*** A letter from the Widdicombe File appears on p 1094 —ED L

USE OF BRL 1241

SIR,—Dr Novick's letter (Oct 29) covers well-trodden ground and adds little except speculation to what we already know By now several thousand strains of *Staphylococcus pyogenes* have been tested, and so far no "celbeninase"-producing organisms have been found This suggests that they are rare if they exist at all, and are considerably rarer than penicillinase-producers were at the time of the introduction of penicillin On the other hand we are all agreed that bacteria often yield mutants which bypass the injurious effects of a chemical agent in some way other than destroying the drug This is an alternative and more common method of developing resistance to an antibiotic In the case of penicillin such mutants can readily be obtained by selection in the laboratory, but have not been shown to be the cause of lesions in man Thus of the two kinds of resistance to penicillin only the one based on the destruction of the drug by an enzyme is clinically important Since 'Celbenin' is a derivative of penicillin having in all probability essentially the same mode of action it would be reasonable to expect that resistant mutants (non-"celbeninase") might also lack pathogenicity, even though retaining coagulase and other characters However, whether this expectation is unfounded, and strains *do* exist which retain sufficient virulence to be of clinical importance and in addition are endowed with sufficient communicability to occupy the biological space in hospitals, can be determined only by carefully controlled clinical observations

The demonstration of celbenin-resistant staphylococcal mutants was probable on general grounds and would be expected to follow the pattern of multiple steps of mutation seen with penicillin, each step resulting in greater resistance As the serum levels obtainable with celbenin at present are more restricted than with penicillin, it is conceivable that first or second step mutants could acquire sufficient resistance in vivo to escape therapeutic action, and yet retain pathogenicity With spraying, however, this is less likely to occur since much higher concentrations can be achieved locally and the mutants succumb to the higher doses of the drug Resistant mutants are not man-made, only selected, and on speculative ground at any rate are more likely to result from therapeutic use than from spraying

Dr Novick says that " it is conceivable that the method might be used indefinitely without unfortunate consequences, and it could be argued that the risk involved is acceptable in view of the advantages This risk must, however, be assessed in the light of the history of the fight against the staphylococcus " We submit that this is precisely what we did—bearing in mind the fundamental clinical problem of penicillin resistance

It must be admitted that a complete victory along these lines is perhaps not in sight, but that should not make one jettison a line of research on theoretical grounds The spraying of carbolic by Lister did not altogether banish hospital gangrene, but while it was in use undoubtedly saved a great number of lives We believe that the discovery of celbenin by the Beecham group was a milestone in the history of antimicrobial agents and will certainly lead to new and powerful drugs in the future In the meantime experiments with spraying should continue until their value is proved or their risk demonstrated on a factual basis

PROGNOSIS AND ANTICOAGULANT PROPHYLAXIS AFTER CORONARY OCCLUSION

SIR,—In their very valuable article of Nov 5 Professor McMichael and Dr Parry suggest that the unusually good 5-year survival-rate of doctors after cardiac infarction is because "no doubt they can take greater care of themselves and avoid undue physical strain" It is surprising that the authors, who are so rightly critical of loose thinking and imprecision in others, should make such a dubious statement What does "taking care of themselves" mean? And what evidence is there that "avoiding undue physical strain" prevents further infarcts?

I submit that a more plausible explanation of the apparent good prognosis in doctors is that their *minor* cardiac infarcts are more often diagnosed than are the minor infarcts of the laity, the symptoms of which are apt to be attributed to "indigestion"

Farnham, Surrey JOHN W TODD

POSTPARTUM PRE-ECLAMPSIA

SIR,—I have read Flight-Lieutenant McFadyen's article of Nov 5 and should like to make the following comments

I have already shown[1–4] that the contracting postpartum uterus provokes renal ischæmia (which incidentally ergometrine might heighten, and this is evident in all the cases reported), that renal ischæmia is responsible for hypertension, œdema, and albuminuria, that hydramnios is an agent provocateur of renal ischæmia (main case), that pre-eclampsia is to be suspected with even minimal signs of the syndrome (main case), that there are many conditions that post partum can masquerade as pre-eclampsia (case 2 certainly being one in point) In fact his case-histories, if interpreted in the light of the data I have provided, amply support the thesis that the uterus resisting tension, which it does post partum also, provokes the uterorenal reflex from which the signs of toxæmia can all stem

Further I have collected sufficient evidence[5, 6] to show that the symptomatology of toxæmia is not comparable to Cushing's syndrome, that as toxæmia mounts so do the corticoids decline, that corticotrophin (A C T H) when given experimentally in human pregnancy does not provoke the syndrome, that eclampsia does occur when the adrenals have been previously extirpated, and that the placental production of corticoids is very small in contrast to that of the adrenals

May I also draw attention to two very important data?

6 Sophian J *Amer J Obstet Gynec* 1954 68, 733

Garrod [7] found that there was an immediate increase in glomerular filtration-rate (G F R) provoked by cortisone experimentally, while there is incontrovertible evidence to show that G F R is much decreased in toxæmia [1]

It would profit obstetricians to study the renal problem deeply To this end may I congratulate you on your enterprise in publishing an account (Sept 17) of the 1st International Congress of Nephrology at Evian, excellently compiled by Professor de Wardener

Worthing, Sussex JOHN SOPHIAN

CHEMOTHERAPY IN CHRONIC BRONCHITIS

SIR,—The paper by Dr Pridie and his colleagues (Oct 1) and the letter by Dr Aspin and Dr Howells (Oct 15) regarding long-term treatment of chronic bronchitis with antibiotics contain findings somewhat at variance with our own The minimum recommended dose of tetracycline or oxytetracycline for the continuous treatment of chronic bronchitis is 0 5 g daily, but we found 1 g per day to be the minimum satisfactory dose A smaller dose is in our view unlikely to be effective in the treatment of the majority of established cases of chronic bronchitis It does not seem to be a fair test of the efficacy of therapy to use a smaller and relatively ineffective dose With a dose of 1 g daily we have shown that the side-effects are much less significant to the patients than the incapacity which results from acute exacerbations of the disease in untreated cases

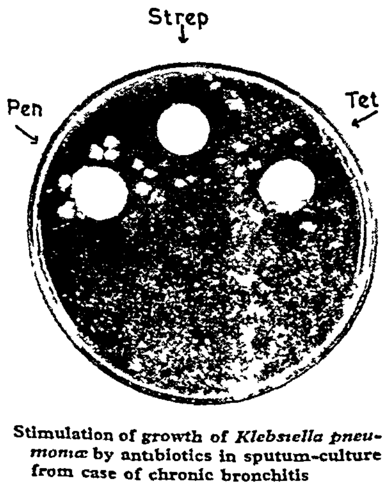
Further, the fullest bacteriological information can be obtained only by examining serial specimens of sputum freshly obtained from the patient We have shown that the correlation of the findings obtained from a single isolated specimen of sputum with the clinical state of the patients is poor The mere isolation of organisms not normally found in the respiratory tract, notably the coliform group, had little or no association with the clinical state of the patients, none of whom was treated in hospital

Departments of Infectious Diseases
and Bacteriology
City Hospital, Edinburgh

J McC MURDOCH
J C GOULD

SIR,—I note the letter by Dr Aspin and Dr Howells with particular interest because I have recently been associated with a clinical trial in chronic bronchitis to assess the value of vaccine therapy in contrast to the normal procedures of chemotherapy and antibiotic treatment

During this trial samples of sputum from some 50 patients were examined and we were particularly struck by the suppression of the normal flora with stimulation of growth of coliforms in vitro, using antibiotic-disc technique (see fig)



Stimulation of growth of *Klebsiella pneumoniæ* by antibiotics in sputum-culture from case of chronic bronchitis

This has led us to believe, as your correspondents suggest, that in treating chronic bronchitis intermittently with antibiotics the suppression of the usual flora may lead to consequent increased growth of the coliform organism

We have therefore persisted in our researches to determine what help vaccine therapy could give

We have been using a polyvalent oral vaccine for this purpose, and have had a great deal of assistance from general-practitioner colleagues in this project Should any of your readers be interested in helping us undertake a larger scale trial we should be grateful to hear from them and supply them with the necessary vaccine

R E DEREK LEIGH

SURGICAL REMOVAL OF BRANCHIAL SINUS

SIR,—I should like to congratulate Mr Allan Small on his article of Oct 22 Whether the condition is fistula or sinus is still a debatable point, but at The Hospital for Sick Children, Great Ormond Street, there have been many true fistulæ

This has been proved by the injection of dye into the track and its detection in the pharynx even before operation

The only point in the article that causes some concern is that related to thyroglossal cysts and their tracks I presume that Mr Small implies that the more difficult part of the dissection includes the excision of part of the hyoid bone and the very careful removal of the proximal part of the track as far as the foramen cæcum

If this point is not strongly stressed I am sure that the recurrence-rate in this condition will increase and lead to many more difficult secondary operations

London, W C 1

S J COHEN

SIGNIFICANCE AND CLASSIFICATION OF FAT-EMBOLISM

SIR,—In his important paper of Oct 15 Dr Sevitt concludes that pulmonary fat-embolism produces no significant ill-effects in previously healthy subjects, and that it does not cause death even in those suffering from shock or blood-loss The validity or otherwise of this conclusion is of great practical importance, for it must influence the rationale of treatment If pulmonary fat-embolism is harmless then the thing to be avoided at all cost is systemic spread of the emboli, for there is general agreement that systemic fat-embolism is potentially a very serious condition Acting on this belief, some German workers [1–3] have practised a prophylactic regime whose object is the maintenance of “ controlled hypotension ”, in order to reduce the risk of pulmonary fat-emboli being forced through into the systemic circulation

I am less certain than Dr Sevitt that pulmonary fat-embolism is innocuous when very severe or when associated with shock or hæmorrhage The absence of a *characteristic* clinical symptom-complex does not necessarily mean that the condition is free from clinical manifestations of any sort It must be conceded that intravenous injection of fat in animals may produce severe effects and even death, although the lethal dose may be considered high there is a considerable species difference in tolerance—the dog, for example, is much more tolerant than the rabbit [4 5]—and results should not be applied uncritically to man Furthermore, there is abundant evidence that processes such as bleeding or the induction of tourniquet shock much reduce the tolerance of animals to intravenously injected fat [4–8] The contrary finding of Armin and Grant [9] stands alone and

may be attributable to the very small dosage which they employed

---

[7] Garrod O, Davies, S H, Cahill, G J *J clin Invest* 1955, 34, 761

1 Fular, W, Kraft, E *Arch klin Chir* 1954 278, 548
2 Fular W Kraft, E *Medizinische* 1956 35 1197

8 Whiteley, H W *J Path Bact* 1954 67, 521
9 Armin J, Grant, R T *Clin Sci* 1951, 10 441

Degrees of pulmonary fat-embolism much more severe than that defined by Armin and Grant as "gross" are not uncommon in man[10] Certainly these are the cases in which fat-emboli are most likely to spread systemically, but it is also in such cases that changes due to pulmonary embolisation are liable to be erroneously ascribed to the effects of systemic involvement Although the pathological changes in the lungs—œdema, congestion, and hæmorrhage—are not in any way specific this does not exclude a causal relationship, and in any event the effects of pulmonary fat-embolism may be circulatory as well as respiratory[11] In my experience a predominantly intra-arteriolar and intra-arterial distribution of fat emboli in the lungs is often associated with a short survival time and an absence of systemic embolisation[10] Any system of grading the severity of embolisation should take cognisance of the size and situation of the emboli as well as of their numbers

While the arrest of fat emboli in the pulmonary vasculature undoubtedly protects the systemic circulation it can hardly be regarded as other than a pathological event, I submit that pulmonary fat-embolism should not be entirely discounted as a cause of illness and even death

TRIGEMINAL NEURALGIA

SIR,—Professor Dechaume has very kindly sent me two papers[12 13] in which he cites the temporomandibular joint as a potential source of true trigeminal neuralgia I was unaware of these papers when I wrote my letter of Oct 1, and I apologise for that omission Professor Dechaume suggests a method of treatment which is new to me—namely, that the sympathetic enervation of the joint is an effective means of breaking into the vicious circle of effect aggravating cause

Colchester

MICHAEL FROST

NICOTINIC ACID IN ISCHÆMIC DISEASE

SIR,—Dr Archibald's criticism (Oct 8) of bus-drivers resuming their occupations after a coronary thrombosis is very pertinent, and it was only after very careful consideration that these drivers were allowed to go back to work Dr Archibald in effect poses the question "Should all patients who have had a coronary thrombosis be forbidden for that reason to drive a car?" With the usual treatment, I should be inclined to say "yes", but I would stress that there is a basic difference with the treatment described in my article of Sept 24

It is interesting that Hunter[14] has described results after nicotinic-acid therapy comparable with my own, except that his dosage is smaller, and he concludes that the improvement in angina is maintained so long as treatment is continued, and that angina gradually returns when treatment is stopped This is in accord with my experience over the fifteen years I have used this treatment, both after infarction and in angina, and it is for this reason that I came to the considered conclusion that ischæmic disease is probably a deficiency disease mainly of nicotinic acid, possibly also of pyridoxine (which forms a coenzyme mediating transaminase reactions and which is probably involved in the enzyme, glutamic-oxaloacetic transaminase) According to this concept, nicotinic acid is a physiological corrective of ischæmic disease

The first patient cited, who is an insurance agent, tells me he makes more than 100 calls a day in his car, and he has done this now for a long time The bus-drivers are seen and examined twice a quarter

Rothwell Haigh,

C E GOLDSBOROUGH

THE VERY DEAF CHILD

SIR,—The complaint of this school, which admits many children who have received various forms of home training, an important aspect of the work of most audiology clinics, is that the period before entry to school for most of them has been inadequately used

Of the present roll of 40 children, 32 have had preschool help of this kind, varying in length from six months to four years 30 of these children had hearing-aids issued by the clinics 2 were deemed too deaf to profit from an aid, though the parents of 1 bought a commercial model

Of the 31 with hearing-aids, only 4, however, were wearing them correctly—i e , continuously and at the right setting with an ear-mould which fitted sufficiently well to enable the necessary volume to be reached without acoustic feedback

At the moment of writing, 21 of the 31 children are wearing their aids properly both in and out of school with corresponding gains in speech improvement and language development Included in the 10 children who do not reach at home the standard of "hearing-aid usage" expected and obtained from them in school are all the 6 children with multiple handicaps The remaining 4 are among our most recent admissions

The fact that so many of these non-hearing-aid-users were trained within a relatively short space to regard their aids as an indispensable ally in their fight against deafness, and not as a barely tolerable encumbrance underlines the need to examine the weaknesses of a form of training which permits so much waste of valuable auditory training time

No teacher of the deaf, as far as I am aware, disputes the immense value of parent guidance and help to the children, particularly during the period between the diagnosis of deafness and the age of 2–3 years Many of us, however, believe that a special nursery school, fully equipped and staffed, where parents are free to come and go and take part in our work, where visiting otologists and psychologists can see the children in surroundings more appropriate than the clinical situation found in audiology units, offers not only the well-known advantages of nursery-school training but also permits conditions suitable for full-time educational and audiological help of the kind appropriate to the children's individual needs In addition, because continuous observation under controlled conditions is possible, it allows a more rapid and accurate assessment of the children's abilities and the nature and degree of their hearing loss, and enables future school placement to be considered on a better-informed basis

Such a special school should cooperate with local hearing schools for selected activities where the children of both schools can meet and play and, under skilled supervision, work with one another (*This is not difficult to arrange*—we do, in fact, work with 3 nearby hearing schools in Woodford in this way)

Miss Whetnall (Oct 15) has referred to the work of Wedenberg[1] who, for the initial period of auditory training, applies a live voice to the meatus of the deaf child without the use of an aid Unfortunately, she omitted to say that Wedenberg himself found that the best subjects for auditory training were the "*gifted children* (my italics) from groups 1a to 2a" (*i e* , children with considerable hearing for the important low frequencies, about 50 db at 250 and 500 cycles) and that children with much less hearing for low frequencies (groups 1b and 2b) were "difficult subjects even when their intelligence is high"

Of the children here for whom we have reliable audiograms 6 come within Wedenberg's groups 1a and 2a and of these 2 only are of above average intelligence

Even more significant is the fact that we are able to train children who Wedenberg found "difficult"—i e , the 1b and

W I CRANSTON

ADMINISTRATION IN MENTAL HOSPITALS

SIR,—With great respect, I wonder whether Dr Kidd (Oct 29) has really found the ideal solution to the problem of medical administration in mental hospitals

As a medical superintendent, before the advent of the National Health Service and since, I have been trying to find the ideal relationship between the holder of that office and his senior colleagues for thirteen years, but have not succeeded yet, although I do not give up hope

We have worked a 3-team system here for ten years, and I support wholeheartedly the doctrine of full clinical freedom for all consultants, indeed, my consultant colleagues here have never complained to me of any interference with their work, but much tact and tolerance are needed on both sides if the hospital is to function smoothly as a corporate entity Dr Kidd tells us that he is responsible to his management committee for the efficiency of the medical work of the hospital How does he equate this personal responsibility with the " full responsibility " of his colleagues ?

One example will suffice How would he deal with a situation such as this, which could happen at almost any mental hospital, any day ? A fellow consultant admits, as an informal patient, an aggressive psychopath, who then rapes the small daughter of a hospital employee, resident on the estate I have been in office long enough to know that the Press, the general public, and indeed the management committee will look to one person only for an explanation, and that person is the unfortunate superintendent It will not help him to say that Dr So-and-So had " full responsibility "

The Mental Health Act has defined responsible medical officers as those in charge of the treatment of the patient Responsible to whom, and for what ? Does " treatment " include control of liberty, food, clothing, social and occupational activities, pocket money, and all the many other aspects of a patient's life ? If so, the result could be chaos with as many " systems " as there are consultants

The duties, responsibilities, and powers of medical superintendents have never been clearly defined No official guidance has been given, presumably in pursuance of the well-known technique of leaving decisions to the man on the spot, with the useful loophole of blaming him afterwards if trouble arises

Responsibility implies authority to take any necessary action, but the authority of the superintendent is vague in the extreme Now that consultants, rightly so, are undertaking greater responsibilities, the functions of the medical superintendent are more than ever in need of clarification This should be done as a matter of urgency, before there occurs some such trouble as that depicted above, with the inevitable recriminations which would follow

Superintendents have " carried the can " for a long time, but, in a changing world, it would be helpful to know something of its new contents

Bracebridge Heath Hospital,
near Lincoln
W A S FALLA

SIR,—Dr Kidd and his colleagues are to be congratulated on having accepted some of the principles without which a mental hospital continuing to have a medical superintendent can hardly be expected to function efficiently These are that the medical superintendent should do clinical work and do it on a basis of equality with his fellow consultants, without powers of interference in their work

I am afraid, however, that Dr Kidd's exposition of the medical superintendent's position in regard to administration involves apparent contradictions and several false or dubious premises, as exemplified by the suggestion that " as far as the hospital management committee is concerned he is answerable to them for the efficiency of the medical work of the hospital " I can only think that in this context " answerable " means " responsible " in which case the proposition is quite untenable A medical superintendent working on a basis of clinical equality with his fellow consultants and without powers of clinical interference cannot be " answerable " for the efficiency of the medical work of the hospital It is very relevant that the Mental Health Act, 1959, Memorandum on parts I, IV to VII and IX, paragraph 29, describes the " responsible medical officer " as " not responsible or answerable for the patient's treatment to any other doctor "

Dr Kidd, having listed various coordinating and facilitating functions of the medical superintendent, all of which, I suggest, can be done as well by the chairman of the medical advisory committee, goes on to say that such work can " perhaps be better done by a man who is permanently appointed to the office, because he has powers of decision and authority not available to an elected chairman of a medical staff committee " These powers and authority appear to derive from his being " officially recognised as responsible for medical organisation " This official recognition has the interesting—and highly undesirable—result that hospital management committees "have to take more notice of his monthly reports than the resolutions of medical advisory committees "

This is precisely the situation which consultants in many mental hospitals are no longer prepared to tolerate, especially in view of the fact that as from Nov 1 such hospitals will operate on the same basis as general hospitals All boards of governors of teaching hospitals and the management committees of most general hospitals recognise and " take notice " of their medical advisory committees as represented by an elected chairman Dr Kidd has made no case why management committees of mental hospitals should not do the same Such recognition should be based on the principle that the senior medical staff in any hospital have an equal and shared responsibility for reaching an agreed policy on all administrative matters affecting the hospital as a whole and that the essential administrative work of the medical superintendent or chairman of the medical advisory committee is to facilitate the carrying out of such agreed policy This may involve difficult negotiations with hospital management committee, regional hospital board, hospital officers, and others In such situations the

may be attributable to the very small dosage which they employed

---

[2] *ibid* p 19 (reference to the definition issued by the Conference of Executives of American Schools for the Deaf, 1937)

Degrees of pulmonary fat-embolism much more severe than that defined by Armin and Grant as " gross " are not uncommon in man[10] Certainly these are the cases in which fat-emboli are most likely to spread systemically, but it is also in such cases that changes due to pulmonary embolisation are liable to be erroneously ascribed to the effects of systemic involvement Although the pathological changes in the lungs—œdema, congestion, and hæmorrhage—are not in any way specific this does not exclude a causal relationship, and in any event the effects of pulmonary fat-embolism may be circulatory as well as respiratory[11] In my experience a predominantly intra-arteriolar and intra-arterial distribution of fat emboli in the lungs is often associated with a short survival time and an absence of systemic embolisation[10] Any system of grading the severity of embolisation should take cognisance of the size and situation of the emboli as well as of their numbers

While the arrest of fat emboli in the pulmonary vasculature undoubtedly protects the systemic circulation it can hardly be regarded as other than a pathological event, I submit that pulmonary fat-embolism should not be entirely discounted as a cause of illness and even death

TRIGEMINAL NEURALGIA

SIR,—Professor Dechaume has very kindly sent me two papers[12 13] in which he cites the temporomandibular joint as a potential source of true trigeminal neuralgia I was unaware of these papers when I wrote my letter of Oct 1, and I apologise for that omission Professor Dechaume suggests a method of treatment which is new to me—namely, that the sympathetic enervation of the joint is an effective means of breaking into the vicious circle of effect aggravating cause

MICHAEL FROST

NICOTINIC ACID IN ISCHÆMIC DISEASE

SIR,—Dr Archibald's criticism (Oct 8) of bus-drivers resuming their occupations after a coronary thrombosis is very pertinent, and it was only after very careful consideration that these drivers were allowed to go back to work Dr Archibald in effect poses the question " Should all patients who have had a coronary thrombosis be forbidden for that reason to drive a car ?" With the usual treatment, I should be inclined to say " yes ", but I would stress that there is a basic difference with the treatment described in my article of Sept 24

It is interesting that Hunter[14] has described results after nicotinic-acid therapy comparable with my own, except that his dosage is smaller, and he concludes that the improvement in angina is maintained so long as treatment is continued, and that angina gradually returns when treatment is stopped This is in accord with my experience over the fifteen years I have used this treatment, both after infarction and in angina, and it is for this reason that I came to the considered conclusion *that ischæmic disease is probably a deficiency disease mainly of nicotinic acid, possibly also of pyridoxine* (which forms a coenzyme mediating transaminase reactions and which is probably involved in the enzyme, glutamic-oxaloacetic transaminase) *According to this concept, nicotinic acid is a physiological corrective of ischæmic disease*

The first patient cited, who is an insurance agent, tells me he makes more than 100 calls a day in his car, and he has done this now for a long time The bus-drivers are seen and examined twice a quarter

C E GOLDSBOROUGH

THE VERY DEAF CHILD

SIR,—The complaint of this school, which admits many children who have received various forms of home training, an important aspect of the work of most audiology clinics, is that the period before entry to school for most of them has been inadequately used

Of the present roll of 40 children, 32 have had preschool help of this kind, varying in length from six months to four years 30 of these children had hearing-aids issued by the clinics 2 were deemed too deaf to profit from an aid, though the parents of 1 bought a commercial model

Of the 31 with hearing-aids, only 4, however, were wearing them correctly—i e , continuously and at the right setting with an ear-mould which fitted sufficiently well to enable the necessary volume to be reached without acoustic feedback

At the moment of writing, 21 of the 31 children are wearing their aids properly both in and out of school with corresponding gains in speech improvement and language development Included in the 10 children who do not reach at home the standard of " hearing-aid usage " expected and obtained from them in school are all the 6 children with multiple handicaps *The remaining 4 are among our most recent admissions*

The fact that so many of these non-hearing-aid-users were trained within a relatively short space to regard their aids as an indispensable ally in their fight against deafness, and not as a barely tolerable encumbrance underlines the need to examine the weaknesses of a form of training which permits so much waste of valuable auditory training time

No teacher of the deaf, as far as I am aware, disputes the immense value of parent guidance and help to the children, particularly during the period between the diagnosis of deafness and the age of 2–3 years Many of us, however, believe that a special nursery school, fully equipped and staffed, where parents are free to come and go and take part in our work, where visiting otologists and psychologists can see the children in surroundings more appropriate than the clinical situation found in audiology units, offers not only the well-known advantages of nursery-school training but also permits conditions suitable for full-time educational and audiological help of the kind appropriate to the children's individual needs In addition, because continuous observation under controlled conditions is possible, it allows a more rapid and accurate assessment of the children's abilities and the nature and degree of their hearing loss, and enables future school placement to be considered on a better-informed basis

Such a special school should cooperate with local hearing schools for selected activities where the children of both schools can meet and play and, under skilled supervision, work with one another (*This is not difficult to arrange*—we do, in fact, work with 3 nearby hearing schools in Woodford in this way)

Miss Whetnall (Oct 15) has referred to the work of Wedenberg[1] who, for the initial period of auditory training, applies a live voice to the meatus of the deaf child without the use of an aid Unfortunately, she omitted to say that Wedenberg himself found that the best subjects for auditory training were the "*gifted children* (my italics) from groups 1a to 2a " (i e , children with considerable hearing for the important low frequencies, about 50 db at 250 and 500 cycles) and that children with much less hearing for low frequencies (groups 1b and 2b) were " difficult subjects *even when their intelligence is high* "

Of the children here for whom we have reliable audiograms 6 come within Wedenberg's groups 1a and 2a and of these 2 only are of above average intelligence

Even more significant is the fact that we are able to train children who Wedenberg found " difficult '—i e , the 1b and

2b groups " whose sense of hearing is defined as non-functional for the ordinary purposes of life ",[2] into becoming talking children with normal attainments and a good command of language Only those, however, we have had from a very early age and who have no secondary handicap

If audiology clinics would transfer to the special nursery school or class at an early age the 1b and 2b children, and those of 1a and 2a group who are not receiving continuous or adequate auditory stimulation either at the meatus or through a hearing-aid, I for one should find less reason for complaint

W I CRANSTON

ADMINISTRATION IN MENTAL HOSPITALS

SIR,—With great respect, I wonder whether Dr Kidd (Oct 29) has really found the ideal solution to the problem of medical administration in mental hospitals

As a medical superintendent, before the advent of the National Health Service and since, I have been trying to find the ideal relationship between the holder of that office and his senior colleagues for thirteen years, but have not succeeded yet, although I do not give up hope

We have worked a 3-team system here for ten years, and I support wholeheartedly the doctrine of full clinical freedom for all consultants, indeed, my consultant colleagues here have never complained to me of any interference with their work, but much tact and tolerance are needed on both sides if the hospital is to function smoothly as a corporate entity Dr Kidd tells us that he is responsible to his management committee for the efficiency of the medical work of the hospital How does he equate this personal responsibility with the " full responsibility ' of his colleagues ?

One example will suffice How would he deal with a situation such as this, which could happen at almost any mental hospital, any day ? A fellow consultant admits, as an informal patient, an aggressive psychopath, who then rapes the small daughter of a hospital employee, resident on the estate I have been in office long enough to know that the Press, the general public, and indeed the management committee will look to one person only for an explanation, and that person is the unfortunate superintendent It will not help him to say that Dr So-and-So had " full responsibility "

The Mental Health Act has defined responsible medical officers as those in charge of the treatment of the patient Responsible to whom, and for what ? Does ' treatment " include control of liberty, food, clothing, social and occupational activities, pocket money, and all the many other aspects of a patient s life ? If so, the result could be chaos with as many " systems " as there are consultants

The duties, responsibilities, and powers of medical superintendents have never been clearly defined No official guidance has been given, presumably in pursuance of the well-known technique of leaving decisions to the man on the spot, with the useful loophole of blaming him afterwards if trouble arises

Responsibility implies authority to take any necessary action, but the authority of the superintendent is vague in the extreme Now that consultants, rightly so, are undertaking greater responsibilities, the functions of the medical superintendent are more than ever in need of clarification This should be done as a matter of urgency, before there occurs some such trouble as that depicted above, with the inevitable recriminations which would follow

Superintendents have " carried the can " for a long time, but, in a changing world, it would be helpful to know something of its new contents

Bracebridge Heath Hospital,
near Lincoln

W A S FALLA

SIR,—Dr Kidd and his colleagues are to be congratulated on having accepted some of the principles without which a mental hospital continuing to have a medical superintendent can hardly be expected to function efficiently These are that the medical superintendent should do clinical work and do it on a basis of equality with his fellow consultants, without powers of interference in their work

I am afraid, however, that Dr Kidd's exposition of the medical superintendent's position in regard to administration involves apparent contradictions and several false or dubious premises, as exemplified by the suggestion that " as far as the hospital management committee is concerned he is answerable to them for the efficiency of the medical work of the hospital " I can only think that in this context " answerable " means " responsible " in which case the proposition is quite untenable A medical superintendent working on a basis of clinical equality with his fellow consultants and without powers of clinical interference cannot be " answerable " for the efficiency of the medical work of the hospital It is very relevant that the Mental Health Act, 1959, Memorandum on parts I, IV to VII and IX, paragraph 29, describes the " responsible medical officer " as " not responsible or answerable for the patient's treatment to any other doctor "

Dr Kidd, having listed various coordinating and facilitating functions of the medical superintendent, all of which, I suggest, can be done as well by the chairman of the medical advisory committee, goes on to say that such work can " perhaps be better done by a man who is permanently appointed to the office, because he has powers of decision and authority not available to an elected chairman of a medical staff committee " These powers and authority appear to derive from his being " officially recognised as responsible for medical organisation " This official recognition has the interesting—and highly undesirable—result that hospital management committees "have to take more notice of his monthly reports than the resolutions of medical advisory committees "

This is precisely the situation which consultants in many mental hospitals are no longer prepared to tolerate, especially in view of the fact that as from Nov 1 such hospitals will operate on the same basis as general hospitals All boards of governors of teaching hospitals and the management committees of most general hospitals recognise and " take notice " of their medical advisory committees as represented by an elected chairman Dr Kidd has made no case why management committees of mental hospitals should not do the same Such recognition should be based on the principle that the senior medical staff in any hospital have an equal and shared responsibility for reaching an agreed policy on all administrative matters affecting the hospital as a whole and that the essential administrative work of the medical superintendent or chairman of the medical advisory committee is to facilitate the carrying out of such agreed policy This may involve difficult negotiations with hospital management committee, regional hospital board, hospital officers, and others In such situations the

elected chairman of the medical advisory committee, speaking for the medical staff, *should* carry more weight than a permanently appointed medical superintendent none of whose authority derives from his colleagues.

---

[2] *ibid* p 19 (reference to the definition issued by the Conference of Executives of American Schools for the Deaf, 1937)

It will be a pity if the tremendous opportunities for advance offered to mental hospitals by the Mental Health Act are lost by a refusal to accept the above basic principles of hospital administration.

OBSTETRIC FLYING-SQUADS

SIR,—Dr. Vartan's letter of Oct. 22 appears to be misdirected, inappropriate and unreasonable. Has no-one ever told him that normal childbirth is a physiological process? To compare it with an operation for varicose veins betrays a distortion of outlook which is all too common.

Hove.
F. V. GRIFFITHS

RADIOCHEMICAL SYNTHESIS OF TRIIODOTHYRONINE

SIR,—Dr. Deutsch (Sept. 10) draws attention to the possible formation of ^{131}I-labelled triiodothyronine by the decay of a molecule of thyroxine containing two ^{131}I atoms, and, with this in mind, discusses the results of Gross and Pitt-Rivers [1-3] and of Braasch et al.[4] His conclusions assume that in these experiments a substantial number of doubly labelled thyroxine molecules is present. Certainly, as regards the work of Gross and Pitt-Rivers, this assumption is incorrect.

The relative numbers of doubly and singly labelled molecules depend on the relative numbers of radioactive (^{131}I) and stable (^{127}I) atoms of iodine present. The position can be more easily illustrated by referring to ^{131}I thyroxine synthesised in vitro by an exchange reaction. In this material labelling can take place in only two atoms, those in the 3′,5′ positions, and not in all four atoms as in the material synthesised in vivo from ^{131}I iodide. Mr. Holloway and Mrs. Pitt-Rivers (Oct. 22) refer to the work of Tata[5] on decomposition products of ^{131}I-labelled thyroxine supplied by Abbott Laboratories. Assuming that this materal is prepared by the method of Gleason,[6] and that it is not diluted with inactive thyroxine after preparation, we calculate, from the quoted maximum specific activity of 50 mC per mg. thyroxine, that 1 mC of ^{131}I is associated with 6·5 µg. of iodine in the 3′,5′ positions. The weight of 1 mC of isotopically pure ^{131}I is 8×10^{-3} µg., and therefore in the 3′,5′ positions of this product 1 atom of ^{131}I is present to approximately 1000 atoms of ^{127}I. This means that for every 2000 singly labelled molecules only 1 is doubly labelled. No detectable amount of ^{131}I-labelled triiodothyronine is therefore likely to arise by the process postulated by Deutsch, and the fact that no ^{131}I-labelled triiodothyronine was detected in Tata's work gives us no information on the correctness or otherwise of Deutsch's postulate.

The position regarding in-vivo syntheses is more complex. Inactive iodine may be present in the so-called "carrier-free" ^{131}I iodide, and dilution with further inactive material may take place during transport in the body to the thyroid gland, and in the thyroid gland itself. Before 1954, ^{131}I produced in Great Britain had a specific activity of about 1 mC per µg. iodine: this implies that about 1 in every 100 atoms of iodine present was radioactive. It was this material that was used in the work of Gross and Pitt-Rivers. Even had no further dilution taken place in the subjects the number of multiple (i.e., double, triple, or quadruple) labelled molecules would be too small to yield a significant amount of ^{131}I-labelled triiodothyronines by decay (assuming that ^{131}I atoms are randomly distributed in the 4 positions of thyroxine, multiple-labelled molecules would form about 1·5% of the total labelled molecules).

The specific activity of ^{131}I produced in Great Britain has increased markedly since 1954. The Radiochemical Centre product is specified as being not less than 10 mC per µg. iodine, and individual batches have given 20 mC per µg. iodine: this latter figure corresponds to 1 atom of ^{131}I in 6 atoms of iodine. The proportion of ^{131}I atoms in fission product ^{131}I supplied by Oak Ridge is probably even higher. Rupp et al.[7] suggest 1 atom of ^{131}I to 1 atom of ^{129}I plus ^{127}I (^{129}I is sufficiently long lived to be considered stable). With material of such high specific activity any dilution with stable iodine in the body before thyroxine synthesis becomes specially important. The factors determining the extent of such dilution are too complex for discussion other than by an expert in the field. In general it seems reasonable to suppose that the extent of dilution will be relatively large. In certain cases this may not be so, and ^{131}I-labelled triiodothyronine might arise in the manner postulated by Deutsch.

PERITONEAL SPLASH: A PHYSICAL SIGN

SIR,—Mr. F. G. Smiddy (Oct. 15) points out that this physical sign can be elicited only in the anæsthetised patient. Many years ago, when I saw more patients with perforated peptic ulcer than I do now, I noticed that in some it was possible to detect a splash while percussing for free gas in the peritoneal cavity. Light and careful percussion in the line of the right nipple with the patient prone will in many cases reveal the gas bubble which obliterates the band of dullness over the liver. At the lower edge of the bubble the pleximeter finger detects a faint splash as the abdominal wall comes into contact with the surface of the fluid behind the bubble. This sign is easily elicited when the perforation is large, there is much effusion in the peritoneal cavity, and the rigidity of the abdominal wall is less than board-like. But then the diagnosis can more confidently be made by other means. In the early case with a small hole, little effusion, and a rigid abdominal wall the sign is not easily elicited.

I concluded that as a physical sign it was of little value, but when present it provided a comforting confirmation of the diagnosis.

SIDE-EFFECTS OF LIBRIUM

SIR,—I read with close attention the correspondence that followed the letter by Dr. Ingram and Dr. Timbury (Oct. 1) about the new drug methaminodiazepoxide ('Librium').

My mind was certainly imbued with that attitude of scepticism and circumspection favoured by your correspondents when I first prescribed these capsules for patients with anxiety states, since I had seen in recent years the much-vaunted advent of a glut of new drugs, the great majority of which were destined to find ere long a dusty tomb on some neglected shelf of the dispensary. I soon came to the conclusion, however, that librium is of much value in the anxiety states. Considerable benefit was obtained in some 5 out of 10 sufferers from morbid anxiety, a result which was the more impressive because not a few of them had previously had little or no relief from other calmative drugs—which clearly mitigates the influence of suggestion. A large majority of those responding to the drug need take the relatively modest dose of 10 mg. three times daily to gain relief from their emotional tension, disagreeable side-effects being exceptional in such circumstances Some of these patients remarked that, unlike other drugs they had tried, librium suppressed their anxiety without producing troublesome somnolence In my hands, the drug has proved more useful for the assuagement of diffuse anxiety than for the relief of the specific phobias of the obsessional neuroses

Although it would doubtless be prudent to postpone *final* judgment I am confident that this drug will soon win its spurs in general practice, and thereby materially reduce the number of cases of anxiety state referred to psychiatric out-patient clinics

HEPATIC SIZE, SHAPE, AND CONTENT

SIR,—We must be grateful for having been reminded of the advantages of peritoneoscopy Though too seldom practised in this country, its value in the diagnosis of hepatic disease and anatomical abnormalities must be recognised

For the certain exclusion of disease, however, it is not so reliable, and this and its other limitations seem to me to indicate the desirability of laparotomy in determining that no hidden metastases are present in the liver

Churchill Hospital,
Headington, Oxford

C GRIMSHAW

NEGATIVE ASSOCIATION OF ABO BLOOD-GROUPS WITH FRACTURED HIP

SIR,—In your issue of Aug 13, Dr Wiener said that Buchwalter had observed an excess of blood-group A in patients with fractured femurs We note that Buchwalter [1] has investigated the ABO blood-group distribution in 910 cases of fractured hips and found no statistical difference when compared with a control group We have examined a small series of patients who had been treated for fractured femoral necks at this hospital All these patients had been blood-grouped on admission as a matter of routine

TABLE I—ABO BLOOD-GROUP DISTRIBUTION

Group	Control series	Intertrochanteric fracture group	Other femoral neck fractures	Total test series
A	1906 *(32 3%)*	56 *(42 8%)*	73 *(33 5%)*	129 *(37 0%)*
B	637 *(10 8%)*	9 *(6 9%)*	22 *(10 1%)*	31 *(8 9%)*
AB	178 *(3 0%)*	2 *(1 5%)*	6 *(2 7%)*	8 *(2 3%)*
O	3177 *(53 9%)*	64 *(48 8%)*	117 *(53 7%)*	181 *(51 8%)*
Total	5898	131	218	349

TABLE II—DISTRIBUTION OF THE RHESUS FACTOR

Rhesus	Control series	Fracture series
Positive	344 *(80 6%)*	279 *(79 9%)*
Negative	83 *(19 4%)*	70 *(20 1%)*
Total	427	349

Table I shows the ABO groups of these 349 patients and those of the control series compiled from data from 5898 consecutive new donor registrations with the West of Scotland Regional Blood Transfusion Service The patients were further subdivided into intertrochanteric fractures and other femoral neck fractures This small series reveals that there is no significant difference in ABO blood-group distribution, although one may be impressed by the relatively high incidence of group A in the intertrochanteric fracture group, there is no statistical difference ($p = 1\ 3$) Furthermore, table II shows that there is again no significant difference in the incidence of the rhesus factor in the fracture patients and those of a small control series of 427 donors

We wish to thank Dr I A Cook, Mr W Sillar, and Dr J Wallace for assistance, and Dr R A Robb for his statistical help

MODERN CLINICAL BIOCHEMISTRY

SIR,—Professor Cappell's presidential address (Oct 15) has called forth a prompt and explosive comment (Oct 29, p 985) from his biochemical colleague at the Western Infirmary

As a biochemist, Dr Hendry is naturally most concerned with Professor Cappell's assessment of the position of chemical pathology in the framework of clinical pathology, and there can be little doubt that he has voiced the feelings of many of the medical and non-medical biochemists who have entered or considered entering the hospital laboratory service These feelings are clearly expressed in their reluctance to apply for posts If Dr Hendry as the head of a teaching-hospital biochemistry department can say it is all but impossible to recruit young science graduates into hospital biochemistry departments, how much more so is this the case in regard to the non-teaching hospitals administered by regional boards, and this at a time when scientists are making fundamental contributions in every branch of industry and many other fields of activity Why should the hospital service alone be denied this advantage? Surely the health of the nation should have at least an equal call on the scientific potential No medical man can view this situation with equanimity, and least of all pathologists whose own work can gain so much more significance and value by close collaboration with chemical studies It would seem worth trying to find the explanation for the unpopularity of hospital work for science graduates

Firstly, the newly graduated chemist, if he is worth his salt, will wish to advance his knowledge and status by acquiring a postgraduate qualification This requires in the case of a PH D that the department in which he works will be recognised by a university department of chemistry or biochemistry as giving proper facilities for postgraduate study together with supervision by a senior member of the staff of these departments In the case of an M SC no university supervision is required, but unless the proper facilities are there the preparation of a thesis will be impossible These facilities consist above all in adequate time—and, in the case of more senior biochemists, assistance—to pursue a research project, and there seems no doubt that the greatest drawback to the hospital biochemistry service in the eyes of would-be graduate recruits is the lack of time and encouragement to undertake research Many pathologists consider biochemical research inappropriate in hospital laboratories, especially in non-teaching hospitals, or, even if they are convinced of its value, are unable to persuade hospital management committees to provide sufficient staff to enable the biochemical graduate to devote time to original investigations He is consequently inundated with routine and repetitive work and soon becomes dispirited and leaves the service, or stays on disgruntled with a grudge against doctors in general and pathologists in particular

No greater catastrophe could befall the pathologist than to lose that intimate contact with the biochemist which promises to solve many problems which neither can solve alone Yet it is clear from Dr Hendry's letter that the pathologists' laudable attempts to weld the hospital laboratory disciplines into a single integrated team are viewed with the greatest suspicion by medically and non-medically qualified biochemists alike The reason for this lies in the question of prospects The young biochemist is not going to sit back and vegetate when he has obtained his postgraduate qualifications He hopes eventually to attain as senior and respected a position in the hierarchy of the hospital staff as he would in industry or other Government scientific establishments, and to have a reasonable chance of running his own department Under the present circumstances he will find his way blocked in both these directions He cannot obtain status comparable with his medical colleagues as long as his method of appointment is that of registrars, technicians, and radiographers—viz, by hospital management committees and not by regional boards Neither can he obtain it—human nature being what it is—as long as his salary is so much less than that of his medical colleagues that he cannot join fully with them in social activities and educate his children similarly As for running his own department, it is generally believed that the Association of Clinical Pathologists considers that the biochemist should be directly responsible to the head of the laboratory in which he works (i e, the senior clinical pathologist), though I am not aware of any published statement of this policy While not suggesting that a non-medical biochemist should be in charge of the other clinical pathological laboratories, I am at a loss to see why a senior biochemist, whether medical or non-medical, should not be in absolute charge of his department, responsible only to the employing authority Of course there will be many matters of a clinical nature which he will want to discuss with the medical pathologists, but surely discussion on terms of parity is the essence of the teamwork which we wish to see in the integrated department of clinical pathology of the future

Yet another explanation for the mistrust by biochemists of pathologists lies in the manner in which the latter are organised for political purposes The Association of Clinical Pathologists has only medically qualified full members How can it be representative of biochemists in general? If it wishes to be considered thus representative, it must give full membership to all hospital biochemists of suitable seniority (which would seem appropriate enough if hospital biochemistry is indeed a branch of clinical pathology!) Similarly if pathological advisory committees wish to be considered qualified to advise regional boards on biochemical matters they should admit senior non-medical biochemists to membership If these suggestions are not attractive to pathologists, would it not be better for them to leave the advising on biochemical matters to the Association of Clinical Biochemists on the one hand and to regional biochemistry advisory committees, still to be formed, on the other? While retaining their role of principal advisor to the authorities on biochemical matters, these organisations would no doubt welcome and benefit by periodic discussions through joint consultative committees with the corresponding pathological bodies

In the meantime, the recruiting position has deteriorated to a stage where it is impossible to fill biochemical appointments even with candidates who are far from ideal There is here a vicious circle The poor quality of the majority of science graduates accepting posts in the hospital biochemistry service has prevented many pathologists from gaining insight into the reliability and potentialities of the best type of biochemist Otherwise it is possible that a far greater degree of responsibility and scope would have been accorded the science graduate Now it is too late, and in despair the pathologists have turned to the young men of their own profession to fill the gap Although there is much that is attractive in the medically qualified biochemist (chemical pathologist), the disadvantages would seem far to outweigh the advantages if he is only going to have one year of fundamental study in chemistry as Professor Cappell suggests With so little experience in chemistry, how will he be able to attract to work under him keen young scientists just leaving university departments of chemistry four years after they have taken their advanced level G C E? If he does not attract them, the standing of our departments of chemical pathology will fall below those of departments of clinical chemistry in other countries

I would suggest it would be far more long-sighted to make the hospital biochemical service attractive to the best young brains in chemistry and biochemistry by introducing the following innovations

(*a*) Every biochemist post advertised (or at least a considerable proportion, which should be specially designated as largely free from routine and repetitive work) should carry with it (i) facilities for obtaining a postgraduate qualification, (ii) reasonable opportunity to reach status comparable in salary and independence with that of medical consultants,

(*b*) *Research should be considered a normal and not an* exceptional activity of biochemistry departments

(*c*) Appointments to senior (principal and top-grade) biochemical posts should be made by regional boards

(*d*) Biochemistry advisory committees should be appointed by regional boards and should always include a professor of chemistry or biochemistry

Although there are many other ways in which hospital biochemistry could be made more attractive, if those mentioned here are implemented there would surely be a most gratifying influx of the best type of scientist into the service, and I should like to see pathologists taking the lead in securing these improvements because it is they who will gain most by having the privilege of working as a team in close collaboration with the finest products of our universities' scientific departments

Midland Centre for Neurosurgery,
Smethwick

A L WOOLF

CHROMOSOME ANALYSIS

SIR,—I was surprised by Dr Stewart's letter of Sept 17 From his statements, one may conclude that colchicine and its derivatives causes heteroploidy and triploidy in animals So far as I am aware, the few cases of heteroploidy and triploidy observed in animals were associated with a highly artificial technique

Colchicine was added to sperm material and the animals artificially inseminated In this way, a few rabbits and one pig supposed to be triploids were obtained[1, 2] However, the accounts concerning these animals have been criticised and their triploid nature is unconvincing and not yet established[3] To sum up, it is apparent from these reports that no polyploid animals have been produced by colchicine[4] Moreover, colchicine does not cause gene mutation[5]

Recently, by intrauterine injections of colchicine into female mice just before mating, Edwards obtained some heteroploid embryos at 3½ days' gestation Chromosome counts of the mature offspring of these females, however, showed no heteroploids[6] Using a different technique, similar results were obtained in rats by French workers A few "heteroploid" embryos were seen at 12th day but none at full-term gestation[7]

The method is, I believe, simple and useful The results are good, and nothing suggests that the intravenous administration of the colchicine derivative is

TREATMENT OF IDIOPATHIC HYPERCALCÆMIA OF INFANTS

SIR,—Many articles have now appeared about the treatment of idiopathic hypercalcæmia of infants A low calcium and vitamin-D intake, a high phytate intake, and the administration of cortisone have been recommended To my knowledge mention has not been made of the possible beneficial effect of total exclusion from ultraviolet rays

The antirachitic effect of sunlight is thought to be due to the activation of 7-dehydrocholesterol in skin This activation may result in the formation of substances with vitamin-D activity equivalent to 1000 or more units of vitamin D per day in infants who are exposed to ultraviolet radiation Possibly this disease has not been reported in Negroes because of the lesser effect of ultraviolet rays on deeply pigmented skin

It seems probable that infants with idiopathic hypercalcæmia are sensitive to very small amounts of vitamin D and it would seem advisable that patients with this disease be excluded from sunlight during those seasons when rays between 280 and 320 µ are present.

Possibly someone with knowledge of the metabolism of vitamin D might render judgment whether infants with idiopathic hypercalcæmia should be excluded from sunlight as part of their treatment

TREATMENT OF OBESITY BY THE HIGH-FAT DIET

SIR,—Bearing in mind case 5, and the large group of patients and friends she appears to represent, can Prof Yudkin and Miss Carey (Oct. 29) offer a 1500-calorie diet that is *permanently* acceptable both *socially* and financially to an adult woman of any age? An overweight woman is conspicuous in a crowd she does not wish to draw further attention to herself by always differing from the group when she is not eating alone

We would be most grateful

Hadleigh, Essex.

ERYTHROCYTE ENZYME DEFICIENCY IN UNEXPLAINED KERNICTERUS

SIR,—I was very interested by the contributions from Smith and Vella[1] and Doxiadis et al.[2] They confirm some observations I had the opportunity to report[3–6] last year

I have so far studied 19 jaundiced newborn children (11 males, 8 females) with unstable G S.H. and/or G -6-P D defect in their erythrocytes In 10 cases exchange transfusion was performed 7 of the transfused children and none of the untreated survived without damage Precipitating factors, such as dangerous drugs, were recognised in only a few cases Severe anæmia was rarely present, on the other hand, jaundice was often associated with severe clotting disturbances, indicating perhaps hepatic impairment, which may be due to the enzyme abnormality itself In fact, as I was able to demonstrate by liver biopsy, G -6-P D activity is decreased in the liver of sensitive individuals as well as in their erythrocytes[6] The observations of Smith and Vella and Doxiadis et al emphasise again the importance of this particular type of neonatal jaundice They also confirm the high incidence of the syndrome in a few families bearing the defect, and this fact suggests that there is a genetic factor in addition to the G -6-P D defect.

A SEVERE ANAPHYLACTOID REACTION TO HYDROCORTISONE

SIR,—Occasional allergic reactions following the local injection of hydrocortisone have been recorded,[1] and in many cases the possibility that associated use of hyaluronidase or procaine was to blame has not been firmly excluded The following case illustrates an allergic response of alarming severity to the injection of 'Hydrocortisyl' (Roussel) 5 ml in a patient who had never had either local or general steroid medication.

No other solution was injected and it was possible to exclude any previous injections (within 2 months) and any tablets or medicines (except 2 tab codein co B P, to which the patient was accustomed, taken a week previously) Similarly no dietary explanation could be discovered

A woman of 50 had, on April 8, 1960, a cup arthroplasty for osteoarthritis of the right hip She made a normal recovery, and was discharged to outpatients on June 17

On Sept 15, during follow-up examination, she complained of pain in the right shoulder A typical moderately severe supraspinatus tendinitis, with early pericapsulitis, was found, and at about 3.30 P M hydrocortisyl 5 ml was injected into the rotator cuff

She had no immediate ill effects, but at 7 30 P M, after supper, she suddenly felt her "face funny—blotchy with lumps, and burning" Red patches appeared on her arms, and she felt sick. She "passed out" and was carried to bed

An hour later, when her doctor arrived, she had regained consciousness, but she was vomiting profusely, had pain in the stomach and loins, and had urticaria, especially on the arms and face Conglomerate petechiæ and bruises appeared over the arms and face She was in a state of shock, with tachycardia, extrasystoles, and a weak pulse. There was much abdominal tenderness, especially in the liver area

She was given anti-histamines ('Piriton'), and she felt a bit better next day, but for 2 days she vomited repeatedly and had diarrhœa and rectal incontinence The stools were fluid and black, and the vomit contained dark blood

She was readmitted to hospital on the 3rd day Laboratory investigations showed hæmoglobin 92%, platelets 300,000 per c.mm, bleeding-time 2 min, clotting-time 6 min, clot retraction after 1 hour normal, prothrombin content 100% of normal, and prothrombin consumption normal The vomit contained dark blood, and occult blood was present in the stools The urine was normal.

Vomiting and diarrhœa ceased on the day of admission, and the abdominal pain and tenderness cleared up within 48 hours She returned home after 5 days

Although intradermal skin tests were unlikely to be helpful so soon after such a severe reaction, they were attempted on Sept. 7 using (1) control solution, (2) a minute dose of penicillin (to exclude penicillin contamination of the syringe used for injection), and (3) hydrocortisyl 0 01 ml An erythematous plaque 0 75 cm. in diameter formed in 24 hours around the site of hydrocortisyl injection, and persisted for 2 weeks, while the control sites showed no reaction

Thus it appears almost certain that this alarming reaction was due to the hydrocortisyl injection. Some

ZOLLINGER-ELLISON SYNDROME

SIR,—With great interest I read the article in your issue of July 16 concerning this syndrome with diarrhœa and malabsorption The gastric-secretion studies before and after removal of the pancreatic islet-cell tumour were particularly striking As the Birmingham group point out, confirmation of their observation with tumours of similar type is important, so you may be interested in the story of a patient Dr G J Verdonk and I reported[1] at a colloquium of gastroenterology in Antwerp in September, 1958

A 66-year-old woman who presented herself in June, 1957, had a continuous pain in the epigastrium, spreading to the back After meals the pain was worse and she complained of heartburn and eructation She had no diarrhœa—on the contrary there was a distinct constipation She never had hypoglycæmic attacks

Examination of this fat healthy-looking woman revealed a resistance in the left upper abdomen which was at first thought to be an enlarged spleen

Erythrocyte-sedimentation rate 15 mm in one hour Hæmoglobin 12 8 g per 100 ml White cells 5400 per c mm, normal differential count Liver-function test normal No occult blood in the fæces Urine normal A fractional test-meal showed considerable hyperacidity free acid 106, total acid 120

X-ray examination of the stomach did not demonstrate an ulcer, but the mucous-membrane pattern was rough On compression of the stomach an area of lack of contrast was visible, possibly caused by pressure from behind The radiologist suggested a pancreatic tumour or cyst Just distal to the duodenal bulb a pseudopodial contour was seen, interpreted as a diverticulum

After six weeks' ulcer treatment with rest, diet, antispasmodics, sedatives, and antacids she was admitted to hospital, because the abdominal mass was still palpable We finally decided on operation On Nov 1, 1957, a pancreatic tumour, 7×6 5×6 5 cm, was removed During the operation the stomach and intestines could not be explored The surroundings of the tumour and omentum were hyperæmic and contained large dilated veins The omentum was containing the tumour and was firmly connected to the surface of the spleen The tumour was removed without vagtomy or gastrectomy The histological diagnosis was "insulinoma"

In September, 1958, nearly ten months after the operation, a fractional test-meal showed that the acid secretion was now reduced to subnormal free acid 0, total acid 16 (maximum)

The Widdicombe File

LXVII —THE DIVISION OF PATHOLOGISTS

DEAR PETER,

I too thought your letter was sound but I think your friend G G, like several of the pathologists, is not entirely familiar with the real function of a college They ask "Can we trust the physicians", meaning presumably the internists, the dermatologists, the pædiatricians, the neurologists, the psychiatrists, and the other *clinicians* in the college, and they talk earnestly about the need for independence But, bless our souls, why do they need to be independent? A college is basically a degree-granting body and also ideally a community of individuals with kindred interests Do we hesitate to take a university medical degree because we doubt the good intentions of the philosophers or theologists who are represented in its court, or do we demand independence so as not to have to eat at table with engineers or lawyers? Maybe the young men want independence at any price because this is the parrot cry of the mid 20th century Fortunately in the college the dermatologists seem to show no distrust of the psychiatrists, and the neurologists are not afraid of being outvoted by the general physicians else there would have to be lots of new colleges What will it benefit the pathologists of tomorrow to have their own college with its expensive library and regalia, portraits and plate? Are pathologists anxious to accept the social and other obligations of a college and to maintain an expensive establishment—for rest assured they will not for long remain content with an attic in Euston but will feel the urge to compete on the perimeter of Regents Park?

Although your arguments were sound one correspondent accused you of talking nonsense His letter reveals the lack of cohesion amongst pathologists and indeed the seed of the next potential split ("Can we consultant biochemists trust the pathologists and bacteriologists?—we must be independent at all costs") What I mean is this, Peter, if the pathologists (and I am using this term generally to include bacteriologists, virologists, chemical pathologists, serologists, forensic pathologists, and hæmatologists—all in fact who are concerned with the laboratory investigation of the patient alive or dead) do not accept this very generous offer of negotiation by the Royal College of Physicians (some claim that it will fail because it is too generous), they may have to wait a long time before achieving the unanimity they require to embark on a new venture Many of the academic pathologists—if what I hear is true—care little whether there is a faculty of the college or a new college

Please impress on your many pathologist friends, Peter, that a faculty will require an appreciable measure of support but a new college will require overwhelming support from all species of pathologists Remind them that a faculty can always be dissolved (I trust that in the event of a faculty both the pathologists and the college will insist on having this in their agreement) but once they embark on a college they will have committed their successors to a life of independence and will have severed connection with their clinical colleagues A recent president of the college, it is said, once invited the pathologists to look forward fifty years They should do this now The rapid growth of specialism, automation, and the increasing excellence of technicians may bring the pathologist of the future much nearer to the patient than he is today and nearer to the clinicians An irrevocable move at this time would be a misfortune

Yours ever,
W W

Parliament

Queen's Speech

In the Speech from the Throne at the opening of Parliament on Nov. 1 it was announced that the Government proposed to increase war pensions, and retirement pensions, other benefits, and contributions under the National Insurance schemes.* They would authorise an increasing level of expenditure on the physical recreation of the young. Awards for students at universities and for those taking comparable courses at other institutions of higher education would be granted on an improved basis. They would introduce a Bill to provide better means of dealing with young offenders, to extend compulsory after-care to prisoners and so to discourage them from reverting to crime, and to improve the management of approved schools.†

Welsh Teaching Hospital

On Nov. 2, on the adjournment, Mr LEO ABSE sharply criticised the plans for this new teaching hospital, which he described as an "ossified hospital design accepted from a septuagenarian architect by assessors led by another septuagenarian architect . . . a design for a hospital for 1950, not as it should be for a 1980 hospital." Wales wanted a forward-looking teaching hospital, it was being proffered a mausoleum.

Going on to offer detailed criticisms, he said that the contemptuous attitude to research was well illustrated by the location and space allocated to the animal house. In defiance of hospital planning, the X-ray department was so embedded within the building that expansion was well nigh impossible. A derisory amount of space was allocated for radioisotopes. A trivial 32 beds had been allocated to mental illness, and there was still no sign of a department and chair in psychiatry being created. But the most dismaying feature was the ludicrous amount of space allocated for research in relation to bed space. The design gave every appearance of there having been a battle for beds between heads of departments.

Other points which he made were: quiet rooms in the noisiest part of the building, the sluice room farthest from the beds most needing its services and unrelated to treatment suite, cross-infection risks increased by infected material being brought into the ward suite for disposal and by inadequate air-conditioning, lavatories concentrated in blocks and not related to bed areas or day spaces, an operating-theatre with a wood-block floor which could never be sluiced clean, eight-storey light wells which meant that wards would be badly lit and have a wretched outlook.

All these blunders and many more, he added, would be housed in a dull cliff-like bulk of buildings unmistakably institutional in appearance.

Miss EDITH PITT, the parliamentary secretary to the Ministry of Health, welcomed the opportunity of discussing the University Hospital of Wales and of replying to some of the criticisms. The fact that it was an undergraduate medical school dictated not only the concept of the work to be performed there but also the site of the hospital, which was to have 650 beds. The scheme must be viewed against the development of acute hospital services in South Wales, which included not only another major acute regional hospital working in the Cardiff area but also major acute hospitals at Bridgend, Pontypridd, and Newport, and others in the Welsh Hospital Board's plans for Merthyr and North Monmouthshire.

The Board of Governors of the United Cardiff Hospitals and the Welsh National School of Medicine desired a hospital integrated with a medical school, with the closest possible working arrangements between the professional and the clinical staff and with the various departments and their research and other laboratories. An architectural competition for an important scheme of this size was thought preferable to selecting an architect, because it was believed that competition would give incentive to a number of architects to think about the problems set by the promoters and that new ideas and techniques might be evolved. Competition, however, could do no more than select an architect and, in a scheme of this size, a fundamental design. The promoters and architect could deal with each other on paper only in broad outline. The details must wait till later. A series of working parties had now been set up to go into the plans of the various units with the architect and with the engineer.

Ward units, outpatient department, lifts and communications, catering and food distribution, training accommodation, the dental school, were all being looked at in this way. The internal design and layout of the ward unit, for instance, had already been replanned to provide better access and better supervision to take account of the latest thoughts on cross-infection, more single rooms had been provided, and the large ten-bed unit had been broken up into smaller units.

This was a normal process which one would expect to take place with any design and similar replanning was going on throughout the hospital. The promoters had examined the design carefully in the light of the numerous criticisms and were satisfied that the completion of the process of preparation of detailed sketch plans, which was now going on, would give them a modern and efficient hospital and a medical teaching centre. She thought it premature at this stage to be too critical of the detailed planning because the details had still to be filled in. It was her earnest hope that, when this hospital was completed, the Welsh people would have a hospital in accordance with their wishes and a hospital of which they might be proud.

QUESTION TIME

Poliomyelitis Vaccination

At Sept. 30, 13,333,000 people in England and Wales had been vaccinated against poliomyelitis under the National Health Service.

---

Obituary

JAMES ERIC PATERSON

M B Glasg , F R F P S

Mr J E Paterson, honorary consultant in neurosurgery to the Scottish Western Regional Hospital Board, died at his home in Rothesay on Oct 26

He was the son of a doctor and graduated from Glasgow University in 1911 as the most distinguished student of his year He spent some years in resident hospital posts, in general practice, and in junior staff appointments in surgery, gynæcology, and anæsthetics before he joined the R A M C to serve in France during the first world war After the war he returned to general practice and part-time specialism, and in 1920 was elected F R F P S

In 1926 he was offered the post of visiting surgeon to Stobhill Hospital, Glasgow, at that time a poor-law institution with 2000 beds for the aged and the chronic sick This appointment required him to give up general practice but gave him no chance to build up a consulting practice, and its acceptance meant a considerable financial loss A colleague relates

" To be poorly paid for tending the ' dregs of humanity ' was no deterrent to this extraordinary little man From the apparent dross he extracted much gold and gained a breadth of experience which few have achieved To suit his poor-risk patients he developed multi-stage operations He quickly learned the need for meticulous preoperative preparation and postoperative care and set up a specialised anæsthetic service In the early '30s his was a lone voice preaching the gospel of biochemistry, and he used the, then, slight resources of that science to the full Blood-transfusions were commonplace in his work when they were seldom thought of elsewhere, and before the late war there was a blood-bank in Stobhill

" He was indeed a general surgeon, whose work ranged from the newborn to the geriatric patient and embraced all specialties His technique was superb Watching him operate was like turning the pages of a beautifully illustrated atlas of operative surgery The neat, the precise, the anatomical attracted him, and he derived much pleasure from his practice of abdominal and reconstructive surgery and from urology, but neurosurgery became his true love This specialty he developed step by step from zero, beginning with attempts to relieve the hopeless cases admitted to Stobhill for terminal care In less than ten years he changed his wards from what was derisively called the ' deid hoose ' to a teaching unit "

The worth of Paterson's work in neurosurgery was soon recognised, and he was appointed neurosurgeon to the Victoria Infirmary He continued to work there until the establishment of the neurosurgical unit at Hillearn in 1940 When the National Health Service was started, he gave up general surgery—not without much heart-searching—and confined himself to neurosurgery

E A T , once one of his students, writes

" Two things were noteworthy about Eric Paterson The first was that he was a great man With the cultivation of a new specialty he combined modesty, enthusiasm, unmitigated frankness about himself even more than about others, unvarying truthfulness, and an uncanny habit of being right in his judgments These are not the qualities which produce an overblown reputation during a man's lifetime, but they indicate the second noteworthy feature about him, which was that his greatness was not as widely known as might have been expected Instead he built a solid foundation of friendship, respect, and those ultimates in admiration—emulation and imitation He threw away opportunities to be grandiose, he gave limelight to juniors, and he demanded no ceremony Such attributes are looked back on after years with love Even his faults were venial, for though his irascibility towards foolishness was legendary he was never hurtful His influence will outlast more brittle reputations Nor for generations will the personal magnetism of the man fade from the minds of his pupils, and his pupils' pupils for even longer the traditions of the units they serve must reflect the imprint of his character "

S A sends a physician's tribute

" Wee Pat was really known and understood by only the surgeons This was entirely proper He belonged to them Maybe physicians—second to none in their admiration for him —like to imagine this frail little man cast in a different role To them it seemed strange that a surgeon should flit through the world on tiptoe—eager, tireless, and radiant His face—specs and all—was a classic for the students sensitive to the physiognomy of intellect Few men revealed in their demeanour, voice, and gesture so vivid a spectrum of human emotions the tranquillity of deep meditation, the turbulence of the exploring mind, the flash of anger, and the smoulder of despair But most memorable of all was his dazzling smile—impish and mischievous—transforming the senior surgeon into a jubilant schoolboy, but eloquent too of his deep humanity James Eric was splendidly endowed with the attributes shared by the artist and the philosopher-surgeon he was in love with the world of beauty; and its glory and splendour were reflected in his imagination Out of these his riches he gave abundantly to patient and colleague alike they rejoice in his talents, they grew and were fortified by his example "

W G also writes of the man as well as of the surgeon

" Wee Pat's knowledge of surgical literature was immense, but surgery by no means filled his life He regarded the world with childlike wonder so that all things were of interest to him In literature, poetry, biography, music, and philosophy he was astonishingly well informed Botany and geology were his delight Sailing was a pleasure with him till it became too strenuous for his years, and then he turned to painting Critical as he was of his own efforts here, he developed his not inconsiderable talents to the full by his customary intense application Because of all his interests he was self-contained, and boredom was unknown to him, but he loved to meet a fellow enthusiast and made many friends through his hobbies

" In his earlier years his sensitivity and his enthusiasm made him a little prickly and intolerant, but the passage of time wore away the sharp edges and left a benign, mature personality as stimulating as ever He had no ambition to order other people's lives, and as a committee man he was a self-confessed failure He could not tolerate scheming and lobbying

" When he retired many groups of friends and associates gave him dinners and presentations The Wee Man was deeply touched and quite bewildered by these tokens His modesty had never allowed him to guess his own greatness nor to realise that he had gained ' that which should accompany old age, as honour, love, obedience, troops of friends ' "

Mr Paterson leaves a widow and two sons, one of whom is in general practice at Forres

Mr C W KIMBELL

G C S writes

" It was in the unpleasant circumstances of the 1940 campaign and then in captivity that Kim's sterling quality of character showed itself in all its brilliant clarity His devoted care of the wounded prisoners and his unswerving loyalty to those who served with him were an inspiration to all Small wonder that he had a host of friends who remember with affection and admiration his generosity and kindliness and his inimitable conspiratorial chuckle To all those the world is now a colder place "

Notes and News

WORLD HEALTH ORGANISATION

AT a meeting in Geneva of the W H O Executive Board, which opened on Oct 25,[1] Dr V Butrov (U S S R) stated that the U S S R would give 2 million roubles in 1961, in addition to its previous contribution, to the malaria eradication special account The Board decided to recommend to the next World Health Assembly that part of the cost of the malaria eradication programme should be financed from the regular budget The Board recommended a supplementary budget for 1961 of $800,000 This includes $100,000 for W H O assistance to the Congo, a further $2,700,000 for the same purpose will be provided by the United Nations

The Board commended Dr M G Candau, the Director General of W H O , for the promptness and efficiency of W H O assistance, and requested that it should continue They also thanked the International Committee of the Red Cross, the League of Red Cross Societies, and Governments which had helped with the emergency health programme

MENTAL ILLNESS IN SCOTLAND

AT the end of 1959[2] the total number of people in Scotland who were under care for mental illness was 20,682 (467 fewer than at the end of 1958) Of those in mental hospitals (including the State Mental Hospital at Carstairs) 14,022 were certified patients (922 fewer than at the end of 1958) and 6385 were voluntary patients (472 more than at the end of 1958) The number of admissions (excluding transfers) during 1959 was 12,428 (990 more than in 1958) Admissions of voluntary patients increased by 1175 to 9977 (80% of the total), but admissions of certified patients dropped by 188 to 2451 8719 voluntary patients (1095 more than in 1958) left hospital during the year Discharges of certified patients (including discharges " by escape ") numbered 1935 (118 more than in 1958) of whom about two-thirds were classified as ' recovered "

At the end of 1959, the total number of certified mental defectives was 8421 (98 more than at the end of 1958) Of these 5107 were in institutions and 2466 under guardianship Admissions of certified defectives to institutions during 1959 numbered 445 (53 more than in 1958) 234 patients were also admitted on an informal basis and 29 patients were transferred from certified to informal status The number placed under guardianship was 111 (8 fewer than in 1958) 215 were discharged from compulsory detention (including those discharged " by escape ")

A special study of readmissions during 1959 showed that of all admissions during the year 4480 (36%) were of patients with a previous admission 1139 were readmitted within three months of last discharge, 886 (7%) within six months, 624 within nine months, and 365 within a year

A NOVEL CLINICAL TRIAL

THE ethics of clinical trials can raise heated discussions wherever doctors meet, whether in lecture hall, laboratory, operating-theatre, hospital common-room, or students' hostel Now, perhaps because his pseudonym covers a man with an F R.C S , Mr John Rowan Wilson has made a medical version of the dilemma of means and ends the centre of his novel, *Double Blind*[3]

A young bacteriologist is carrying out on a tropical island a double-blind trial with a vaccine against a form of encephalitis The trial is being financed by a German drug firm which hopes to patent part of the manufacturing process The island is an isolated primitive community under the tutelage of the Colonial Office In obtaining permission to carry out the trial in its hospitals and clinics official channels have been by-passed Though the natives normally give their permission before receiving the vaccine, it is unlikely that they realise the significance of the request On the other hand, " South Atlantic " encephalitis is an endemic and dangerous infection and its control would be an enormous benefit to the community Two deaths occur which may or may not be due to the vaccine A Catholic priest complains The Colonial Office, uneasily aware of lapses in protocol, if not in morality, send out a doctor to report on the trial

This complex epidemiological situation contains many of the important issues which beset the conscience of the research worker It is further complicated by the tense personal relations of the doctor, the bacteriologist, and his wife Their personal problems are solved by the novelist's manipulation of the plot The questions of general principle inevitably remain unsolved, but it is to their intelligent presentation that the book owes much of its unusual interest

BIOLOGICAL ENGINEERING SOCIETY

THE first scientific meeting of this society was held on Oct 15 at the National Institute for Medical Research, Mill Hill In his opening address, Sir Charles Harington drew a parallel between the state of biological engineering today and biochemistry half a century ago Perhaps in the years to come, he said, a fusion of the two disciplines of biology and engineering might result in biological engineering becoming as acceptable as biochemistry today In the meantime, advances in biological and medical science depended greatly on advances in engineering and instrumentation, and the society was making a valuable contribution by enabling biologists and engineers to work more closely together Prof R F Woolmer, the president of the society, thought it appropriate that this first meeting should be held at the Institute, for its work and organisation was a good example of the way in which engineers could work together with biologists About 100 people attended the meeting, and the programme of demonstrations was planned to give a cross-section of the subjects which the society hopes to cover

SPASTIC SCHOOL-LEAVERS

ONE of the most useful qualities of voluntary organisations is their refusal to leave fairly well alone The British Council for the Welfare of Spastics, now that they are satisfied that there is no longer a general shortage of school places for spastics, have turned their attention to the difficulties which these young people face when they go out into the world[1] A pilot survey made by the council gives a depressing picture

> Of 34 recent school-leavers only 9 were thought to be capable of becoming fully self-supporting Though 7 of these were in work only 3 were in jobs with reasonable prospects None had received any training Another group of 16 were described as ' doubtfully employable , and of these 5 were in jobs and 5 awaiting training None are ever likely to become financially independent The remaining 9 were expected to be unemployable

Thus, in all, only 12 were employed and not in very satisfactory jobs The highest wage earned was £5 10s , and even those of average intelligence were doing work well below their capabilities Of the 22 who are not in jobs some are in institutions or awaiting admission Others live at home and some attend occupation centres Some are waiting for training All are thoroughly under-occupied and lack enough interests to fill their days, and this leads to mental and physical deterioration In or out of jobs, they seem to lack friends and social life Clubs for the handicapped do not attract them, for whether practicable or not, they want to go out to work like other youngsters They seem to lack realism about their capabilities and of standards in the outside world, perhaps because of the inevitably sheltered atmosphere of the schools in which they were educated

The numbers in the survey are small, and the Council offer the results not as a basis for recommendations but as evidence of need. The results are a salutary reminder that, like the rest of us, the handicapped are living longer and that the support we give them must be continuous and flexible, keeping pace with their changing ages and circumstances

University of Cambridge

On Oct 29 the following degrees were conferred

M D—P A J Ball J H Cule, P C Gautier Smith, J C Kelsey, C G Rob (by proxy), David Wise
M B—T J Willis

University of Birmingham

Dr R L Edwards has been appointed senior lecturer and first assistant in the department of obstetrics and gynæcology

University of Glasgow

On Nov 5 the degree of M D was conferred on William Cullen (with commendation) and on Joseph Sluglett

University of Queensland

Dr T J Rendle-Short, lecturer in child health in the University of Sheffield, has been appointed to the newly established chair of child health in this university

Royal College of Physicians of London

Dr K D Keele will give the FitzPatrick lectures on Tuesday, Nov 29, and Thursday, Dec 1, at 5 P M, at the college, Pall Mall East, S W 1 His subject will be Evolution of Clinical Methods in Medicine

Royal College of Physicians of Edinburgh

A meeting of college was held on Nov 1, with Dr A Rae Gilchrist, the president, in the chair

A Hill Pattison-Struthers bursary for 1960 has been awarded to Dr Philip Lanzkowsky and the Jean Hunter prize for 1960 to Dr A W E Soysa

The following were elected to the fellowship

Eric James M M Whittet, Keshavarao Krishnarao Datey, H G H Richards, H R L Fraser, A B Hegarty, J S Robson, J A Loraine, Tadepalli Shamsunder Row, R C Jackson, Velva Schrire Agnes L Scott, B C Sinclair-Smith, A C Kennedy, John Butler, K L Stuart, Arthur Jarrett A R Somner D S Nand, S L A Manuwa, J H Hutchison, D F Cappell, J H Walters, K W Donald, A W Woodruff, Eric Samuel

The following were elected to the membership

C W Kidd, A P Meiklejohn, R M Vanreenen, Krishna Rao Purohit, H L Davis R W McConnachie, Thambippillai Vamadevan, A R Adams, N R Young William McQuaker Sean O Reilly, L H Harris D G B Powell, David Jacobson, Elaine M Belton, Ralph Emery, J K Binns, Sheikh Muhammad Haneef, Ram Singh, G C Timbury, Joseph Gatt Barry Lewis, Anand Mohan Sur, R G B Williamson, Hamdy Mahmoud El-Sayed, Samir Mohamed Omar Hilal, Mookencherry Cherian Mathews, A I Rae Frank Tsu Chang Hu David Burrows, Nedumchalil Markose Mathai Baboobhai Rambhai Patel B S David Achyut Govind Motiwale, Peter Taylor, N P Burns, Kishin Hingorani, J D Woolridge, Boon-Kheng Khoo, I R Lawson Pandramajal Narayanappa Krishnamurthy Khalid Haji Aboo Mitha Nalkundad Kyathappanavara Channappa, R A Osborn, Dona Priyalatha Wijesinghe, M D Bowie, Lotfy Labib Basta, Vishnukumar Gupta Erasmus Lynghdoh, M G Dunnigan, Iain Michie, Harischandra Ranasinghe, Ekpo Edet Eyo, Chenniah Javaraya Bhakta Ram, Krishnadhan Datta, Susil Chandra Munsi Subrata Sen, Cheruveetil Kochukutty Gopi Mohammad Ata, J A Waddell, Bhim Sen Ghisaram Singhal, Chandidas Gupta, Joseph Levin, E S Garnett, Gulamabbas Juma Ebrahim, W H S George, J A McBride

Heberden Society

Dr J J Bunim will give a Heberden oration on Friday, Dec 2, at 4 15 P M, at the Wellcome Foundation, Euston Road, London, N W 1 His subject will be a Broadened Spectrum of Sjögren's Syndrome and its Pathogenetic Implications

North West Metropolitan Regional Hospital Board

Lord Moynihan has been appointed chairman of this board

Albert Lasker Grants

The American Public Health Association have awarded grants to Dr F H C Crick, of Cambridge, and Dr M H F Wilkins, of London, for their work on processes governing heredity in living cells and viruses, and to Prof Lionel Penrose for his contribution to the development of human genetics and his findings on the effect of nuclear and other radiation on human beings and their offspring

On Wednesday, Nov 16, at 5 15 P M, at the Royal Free Hospital, Gray s Inn Road, London, W C 1, Sir William Morrow, physician to the Royal Prince Alfred Hospital, Sydney, will speak on ulcerative colitis

Applications are invited for grants for research into diabetes mellitus and associated diseases Further particulars may be had from the secretary of the research grants committee of the Association, 152, Harley Street, London, W 1

DISEASES OF THE BASAL GANGLIA

THEIR RELATION TO DISORDERS OF MOVEMENT*

D. DENNY-BROWN
O.B.E., M.D. N.Z., D.Phil. Oxon., LL.D. (hon.), F.R.C.P.
PUTNAM PROFESSOR OF NEUROLOGY,
HARVARD MEDICAL SCHOOL, BOSTON, MASS.

I

THE term basal ganglia has no precise limitation, having been used by the older anatomists for the large grey masses at the base of the brain, including the optic thalamus. In the present century the thalamus has been excluded, and the use of term limited to the caudate nucleus, the putamen, and the globus pallidus. For neuropathological reasons certain closely related subthalamic nuclei are often included. I shall not here discuss the intricate, and in part disputed, interconnection between these structures. The most important of these are shown diagrammatically in fig. 1, which is designed to emphasise the reflex pathway from the intralaminar (I.L.) and centrum medianum (C.M.) nuclei of the thalamus to the globus pallidus, putamen, and caudate nucleus, and the efferent connections of these nuclei with the subthalamic nucleus (S.), the reticular formation of the midbrain (M.B.R.), and the substantia nigra (S.N.). Short pathways connect these scattered subthalamic structures with the important motor reticular formation of the brain-stem. The caudate nucleus, putamen, and globus pallidus also receive pathways from various areas of cerebral cortex. The caudate nucleus contributes an important pathway to the lateral thalamus. Though the basal ganglia are closely interrelated with the cerebral cortex in this way, they preserve both structure and function in its absence. This independent reflex activity is responsible for much of the behaviour that distinguishes the decorticate from the decerebrate animal.

My first objective is to define the degree to which diseases affecting the different ganglia produce consistent physical signs. Before 1895 there was no hint that damage to this region of the brain had any specific effect, though in the time of Hughlings Jackson it was customary to regard the basal ganglia as the seat of regulation of those simple spasms that remain when the cerebral cortex is destroyed. The first hint that specific disorders of movement are related to limited disease of these ganglia appears to have been the excellent description of congenital double athetosis by Anton in 1896, with the related scarring of the outer putamen on both sides. The most convincing demonstration, however, was the description of progressive lenticular degeneration by Kinnier Wilson (1912), providing a dramatic demonstration of the relation of limited lesions of these ganglia to rigidity, distorted posture, and tremor. Only then did the earlier descriptions of outfall of nerve-cells in the globus pallidus in paralysis agitans by Jelgersma (1908), and the comparable atrophy of the caudate nucleus in Huntington's chorea described by Alzheimer (1911), assume real significance.

As had so often happened in relation to clinicophysiological correlation in cerebral disorders, the rush to stake out claims on the anatomical terra nova outran both the available physiological philosophy and the necessary neuropathological experience. Indeed the Croonian lectures of Kinnier Wilson (1925) are wholly devoted to a sobering criticism of the massive superstructure that had already burdened the topic. The difficulties that pervade the subject are derived from the very general nature of the pathological processes that affect these structures, the kaleidoscopic variations in resulting symptomatology, and the poorly understood part that the ganglia play in normal cerebral function.

Hepatolenticular Degeneration

The striking demonstration of lenticular cavitation in hepatolenticular degeneration (Wilson's disease), though important in other respects, was most misleading in its implication that the disease process was itself localised. The widespread nature of the gliosis that accompanies all forms of the disease (Hall 1921) is now generally recognised. That the disease is an inborn error of metabolism resulting in accumulations of protein-bound copper in many organs, particularly the liver and nervous system, is also well understood. Within the nervous system greatly increased concentrations of copper are present in the putamen and thalamus, and to a less extent in the cerebellum and cerebral cortex (Cumings 1948, Spillane et al. 1952, Cartwright et al. 1954). The striking improvement that can follow removal of small amounts of copper from the body by chelation indicates that, in some cases, a

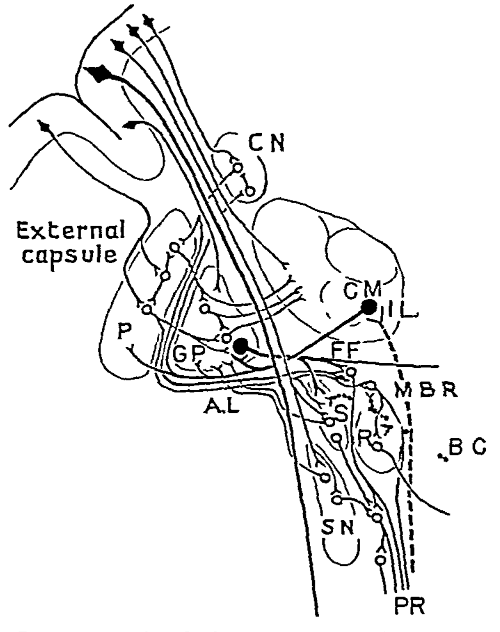

Fig. 1—Diagram of the chief connections of the basal ganglia.

The efferent systems of the globus pallidus (G.P.), putamen (P.), and caudate nucleus (C.N.) pass through the ansa lenticularis (A.L.) to the fields of Forel (F.F.). There they reach the subthalamic nucleus (S.), the scattered nuclei of the midbrain reticulum (M.B.R.), substantia nigra (S.N.), and red nucleus (R.), with connections to the reticular nuclei of the pons (P.R.). The reflex circuit has an afferent limb in the lemniscus and ascending tegmental tracts (represented as a broken line) through the intralaminar (I.L.) and central (C.M.) nuclei of the thalamus. The midbrain and subthalamic reticular nuclei receive terminations of the brachium conjunctivum (dotted line B.C.).

---

* From the Croonian lectures for 1960, delivered before the Royal College of Physicians of London on Feb. 23 and 25.

relatively small fraction may in time interfere with vital enzyme function In the juvenile type such improvement is unfortunately offset by other unknown factors

When the symptoms start after the age of 20 the disorder appears as flapping tremors at the wrist and shoulders, which are absent at rest and provoked by movement The very diffuse gliosis of the nervous system that is then present makes it impossible to relate such incoordination to damage to any particular structure The tremor has some features in common with that caused by other types of damage to the midbrain reticulum The fate of such cases is usually determined by the severity of the associated hepatic cirrhosis If they survive for long a generalised mild muscular rigidity ultimately appears in all limbs, predominantly in flexion, in association with severe dysarthria and dementia There is then widespread fibrosis of the cortex, thalamus, and basal ganglia

In the juvenile types of Wilson's disease involuntary movements of a different kind occur These are at first small involuntary lapses in posture At or about the same time the natural facial expression changes, the mouth is held more constantly open, and the eyelids blink seldom The changes in expression, associated with slight postural changes in the hands in the nature of overextension of the fingers (fig 2*a*), long precede the dysarthria and facile smile that were noted by Wilson Gradually the postures of the limbs become more stiff—at first in walking, when they tend to overextension first on one side and then on the other—leading to an awkward clumsy gait A plastic rigidity is then apparent in the affected limbs It is at this time that a slurred dysarthria is usually first noticed As the disorder progresses first one then the other arm becomes flexed in a hemiplegic posture, and the lower limbs become more constantly extended As these postures develop, tremor usually appears In some patients the tremor is that of the adult type of the disease, a rapid alternating flapping at the wrist and fingers In others it begins as athetosis, with slow swings from overextension of the hand to overflexion In this type the swing of movement may in time accelerate and make gradual transition into a parkinsonian type of tremor In most patients the swings of athetoid movement become slowed by increasing rigidity, the hand becomes more continually flexed and the ankles overextended as part of the terminal hemiplegic dystonia that was illustrated so well in Wilson's original description

I should like to draw particular attention to the evolution of the terminal dystonic state in hemiplegic attitude, for this has, in my experience, been invariably present when bilateral rarefaction or frank cavitation of the putamen has occurred In time there is yet a further change in the symptomatology, in the nature of lessening of the hemiplegic rigidity, and its conversion into a state of mild general flexion (fig 2*b*), with flexed wrists and extended fingers and ankles If the patient is lifted from the bed, the limbs still stiffen, resuming in some degree the earlier rigid hemiplegic posture (fig 2*c*) I shall later return to the significance of these postures, for they are a key to much that is obscure in the pathophysiology of the basal ganglia

Huntington's Chorea

It is not necessary here to outline the characteristics of Huntington's chorea except to point out some distinctive

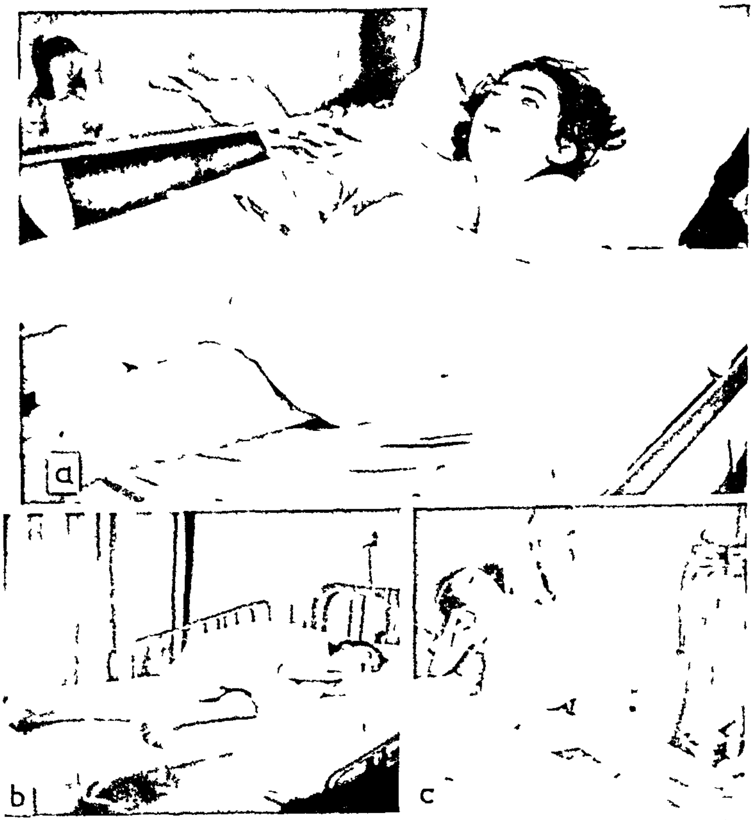

Fig 2—To show (*a*) the early abnormalities of posture in a patient of 16 beginning to show signs of hepatolenticular degeneration *In (b) is shown the posture of the* same patient 4 years later in an advanced stage of the disease (note the overflexed wrists with extended fingers) If the patient is lifted from contact with the surface of the bed (c) all limbs stiffen and the lower limbs extend

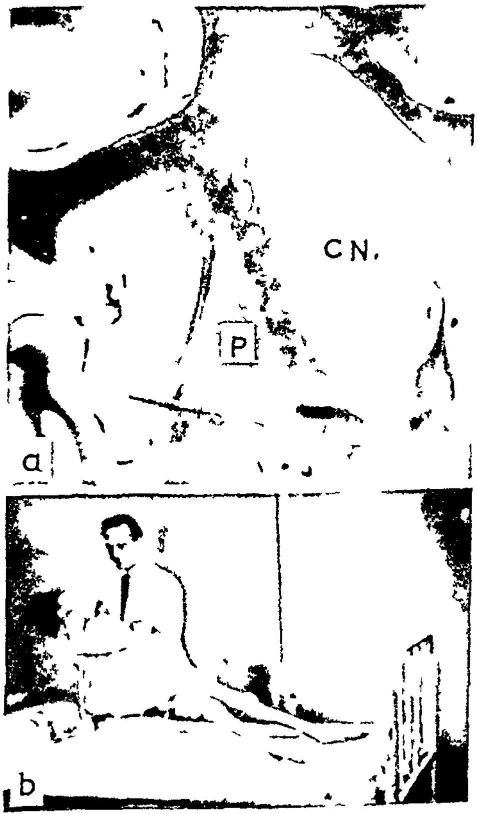

Fig 3—To show (*a*) the extreme atrophy of the caudate nucleus (C.N) and to a less degree of the middle third of the putamen (P) in an advanced stage of Huntington's chorea; and (*b*) the rigid posture when such a choreic patient is raised from the bed

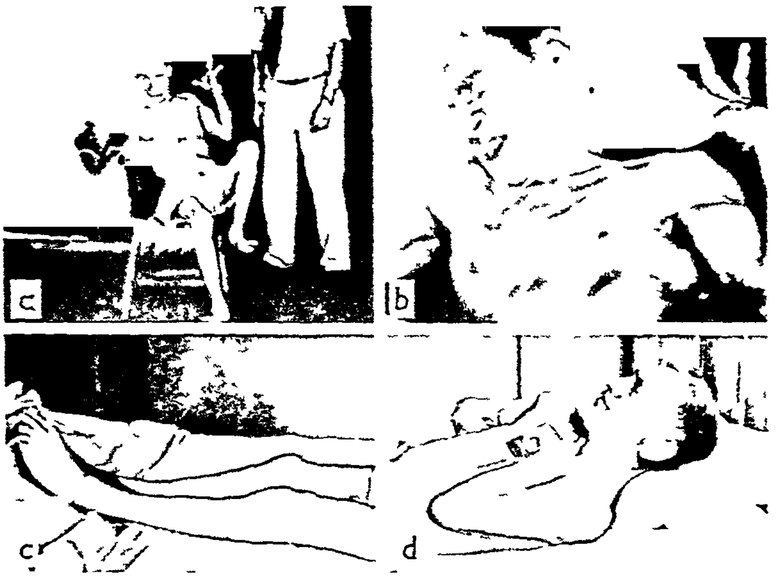

Fig 4—To show the "mobile spasm" with athetosis of hands and lips (*a* and *b*) in double athetosis. In the terminal stage a rigid posture of extension of the lower limbs (*c*) and flexion of the upper limbs (*d*) replaces the "mobile spasm"

features of the involuntary movements and postures. The movements are essentially labile and haphazard in distribution. I have described elsewhere (Denny-Brown 1950) how the movements of the hands and arms gradually assume the swings of posture seen in athetosis, though at a faster rate. This is first seen in walking. The movements of the lips and jaw gradually develop the wider amplitude, with associated incoordinate action of the platysma muscles, that is a feature of double athetosis. For a long time the limbs are hypotonic, but the posture gradually becomes more stooped, and in late stages of the disease rigidity may appear, with more characteristic slower athetoid movements. The posture is then a rigid hemiplegic attitude, which is greatly intensified by raising the patient from contact with any surface (fig 3). The arms are strongly flexed, and the legs and ankles stiffly extended. This posture is the same as that mentioned as a late stage of Wilson's disease.

When the onset is early, rigidity may be the most prominent symptom (Kehrer 1928). There is then close resemblance to parkinsonism, including pill-rolling tremor of the fingers (Fleischhacker 1924, Josephy 1936). In a few patients unmistakable parkinsonism develops later in life (Chandler et al. 1960) though the lower limbs are, in my experience, more often extended stiffly than flexed in the usual parkinsonian posture. Besides atrophy of the frontal cortex shrinkage of the caudate nuclei is almost universally present, together with some loss of cells in the middle third of the putamen (Marie and Lhermitte 1914, Dunlap 1927) with pallor of the corticostriate and striopallidal systems (fig 3). A condition of fibrous scarring of the putamen, called "status fibrosus" by the Vogts (1920) and Jakob (1923), has been found in the cases presenting rigidity (Bielschowsky 1919, Terplan 1924, Freund 1925). In some cases the degeneration extends to the globus pallidus and subthalamic nuclei. The extrapyramidal manifestations of Huntington's chorea, as with Wilson's disease, are seen to form a spectrum of types of movement disorder in relation to an evolving pathology, ranging from early myoclonic twitchings in some cases to torsion spasm and rigidity and, more rarely, parkinsonism. The most characteristic choreic movements reflect only the usual early affection of caudate nucleus and frontal cortex.

Double Athetosis

The case selected by Vogt (1911) as the prototype of striatal disease presented an unusually well-localised marbled scar in the outer segment of the putamen on both sides. The clinical symptoms are usually a bilateral labile type of athetosis affecting all parts, but particularly the hands, mouth, and neck, and present from the first year of life. The condition is now well recognised, and is usually called "double athetosis" (fig 4*a* and *b*). The scar tissue appears to be a static inactive process. Many follow Courville (1953) in attributing it to anoxia at birth. In several cases there has been similar scarring of the cerebral cortex (Alexander 1942), but there is no doubt that the lesion in the putamen can occur alone, and in association with a bilateral mobile type of athetosis present from soon after birth. In many cases rigidity of the limbs appears later, gradually slowing the athetosis to "mobile spasm" and leading ultimately to intense flexion of the upper limbs and extension of the lower limbs (fig 4*c* and *d*). When rigidity has complicated athetosis in this way the scarring of the putamen is usually more extensive, but few cases have been analysed from this point of view.

Dystonia Musculorum Deformans

In its progressive form, dystonia is the most striking and grotesque of all neurological disorders. The progressive small spasms of flexion of a lower limb, or alternatively of torticollis, that are usually the first manifestations in early childhood, first appear as additions to movements such as walking. Only when continuous maintenance of the abnormal posture occurs is the dystonic condition recognised. Though I have earlier indicated the essentially athetoid character of the beginning of the disorder (Denny-Brown 1945), its relation to athetosis is still overlooked, for the first signs are spasms in willed movement rather than involuntary movements. As the disorder progresses new intermittent elements of athetoid spasm make their appearance, they are set up, like the first, by any stimulation or attempted movement, but they gradually become more constant. The cumulative steady spasm of flexion of proximal joints has added to it extension of the fingers and toes, retraction of the jaw and lordosis. The later addition of intermittent spasm in antagonistic muscles followed by continued contraction in antagonists, leads to the great deformity. Unless there is accompanying spasticity, the asymmetrical postures and movements can be profoundly changed by altering the areas of body in contact with the bed or examining table. If the patient is lifted free from all contact with the body surface, save for support under the axilla, the upper limbs flex and the lower limbs extend in hemiplegic posture (fig 5). If movements have been in progress they cease when the child is suspended. When the patient lies on one side the lowermost limbs extend and the uppermost flex. These changes indicate that reflex effects from contact between the body and supporting surface are important factors in the production of the abnormal movements and postures

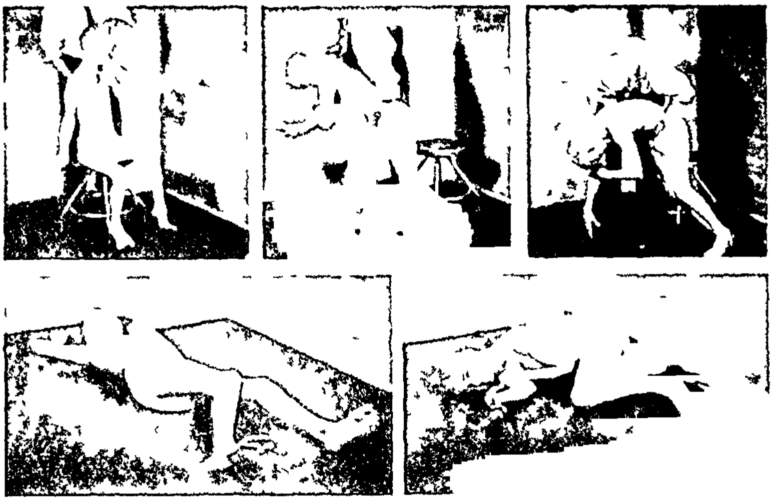

Fig 5—Dystonia musculorum deformans To show the abnormal attitudes and their modification by suspending the patient and by lying on a flat surface
(Photographed at Wrentham State School, with kind permission of Dr Carl Quinn)

Dystonia is a symptom complex that has many causes, but the irregular and grotesque progressive deformity described above, with cumulative development in one body part after another, has not been clearly correlated with pathological processes other than status marmoratus, which closely resembles the lesion of double athetosis, but usually involves the thalamus and cerebral cortex in addition to the putamen Thomalla (1918), Wimmer (1921), Jakob (1932), and others have reported the lesions of Wilson's disease in relation to relatively symmetrical dystonia Lethargic encephalitis was undoubtedly the cause of many cases of asymmetrical dystonia of partial and arrested types The cases of Cassirer (1929), Jakob (1923), Marinesco and Nicolesco (1929) and Laruelle and van Bogaert (1929) showed milder changes in the form of pallor of the globus pallidus and cell loss in the putamen There is some possibility that such cases are postencephalitic

More Diffuse Lesions of the Basal Ganglia

From the great variety of diffuse degenerative processes that affect the basal ganglia, I have singled out Wilson's disease, Huntington's chorea, and status marmoratus as examples where rigid " dystonic " states can be related to relatively localised destruction of the putamen Before turning to the problem of parkinsonism, we should briefly review some of the other types of diffuse pathology that affect the basal ganglia These are all rare and obscure syndromes, and I shall here only comment on the type of movement disorder in relation to anatomical lesion

Calcification of the basal ganglia (Fahr's syndrome) is an affection of the walls of small blood-vessels of these organs that may reach considerable intensity, even to the degree of visibility in skull X-rays (Fahr 1930), without neurological symptoms There may or may not be associated hypoparathyroidism (Sugar 1953) The neurological disorder that eventually appears is a generalised rigidity, most commonly beginning in the lower limbs (Fritsche 1935, Chavany et al 1949), with or without athetoid movements Parkinsonism developed in middle life in the patients of Jakob (1923) and of Alexander and Tucker (1949) The calcification in such cases begins on the border between the putamen and globus pallidus In a remarkable familial case of my colleague, Dr Paul Yakovlev, such calcification resulted in dysarthria with intense ridigity of all limbs in flexion

Similar flexion postures eventually result from diffuse *lipidosis* of the juvenile type (Sjogren 1931, Watson and Denny-Brown 1953) Similarly in the *Hallervorden-Spatz syndrome*, where deposits of iron-containing pigment accumulate in the globus pallidus, thalamus, substantia nigra, and dentate nuclei, there results a diffuse rigidity of the limbs in flexion, with or without athetosis It is also notable that, both in this syndrome and in lipidosis, there is a liability to sudden jerks of the limbs in flexion (myoclonus) as a prelude to the eventual postural change

The Enigma of Parkinsonism

The most common of extrapyramidal syndromes—parkinsonism—presents the most difficult problems in this whole group of diseases There is still no agreement as to the essential change in anatomical structure

The pallor of the ansa lenticularis and related efferent pathways of the pallidum, and the progressive loss of cells in the globus pallidus and, to a less extent, the striatum, described by Jelgersma (1908) and by Lewy (1913), have been found by many others (Lhermitte and Cornil 1921b, Bielschowsky 1922, Jakob 1923, Foix and Nicolesco 1925) In 1919 Tretiakoff drew attention to some loss of cells in the substantia nigra in paralysis agitans, as well as to the severe destruction of this nucleus in postencephalitic parkinsonism This feature of the disease has gained greater emphasis in the past twenty-five years (Hassler 1937a and b, Benda and Cobb 1942) Greenfield and Bosanquet (1953) have confirmed scattered cellular changes in the locus cœruleus of the pontine tegmentum, as well as in the substantia nigra, found earlier by Foix and Nicolesco, and by Hassler In his posthumous textbook on neuropathology, Greenfield (1958) states that the lesions in the globus pallidus, though constant and sometimes severe, are " essentially those of senility "

Our own pathological material in the Boston City Hospital consists of 21 cases, 5 of them are clearly postencephalitic, 7 have atherosclerotic lacunar lesions in the putamen, and 9 could be clearly calssified clinically and pathologically as idiopathic paralysis agitans Only 2 cases had been subjected to serial whole-brain sections, but multiple sections of the basal ganglia and midbrain of all the others were available for study

All cases of parkinsonism exhibited some degree of pallor of the globus pallidus and the ansa lenticularis, in sections stained for myelin sheaths The corresponding loss of nerve-fibres was more impressive than loss of nerve-cells In *paralysis agitans* the pallor was usually uneven, and foci of loss or thinning of myelin sheaths were particularly evident in the outer pallidum near the external lamina In Nissl sections such foci were represented by small inconspicuous areas of loss of cells from the otherwise evenly scattered pattern of pallidal cells In 2 cases small concretions were present in the ground substance, not directly related to the foci Gliosis was mild in degree In no case was there any evident disease of blood-vessels, other than some mild siderosis in 2 cases (a change commonly found in the globus pallidus after middle life) In one patient who died after a head injury all striopallidal and corticopallidal fibres stained very poorly compared with the pallidal efferents in the ansa lenticularis In the most severely affected cases all the pallidal cells were shrunken and stained poorly, and their lipid content appeared to be increased in relation to their size In 5 cases, and doubtfully in 2 the substantia nigra showed the small lesions described by Hassler No cell or fibre lesion was found in the nigra in 2 cases

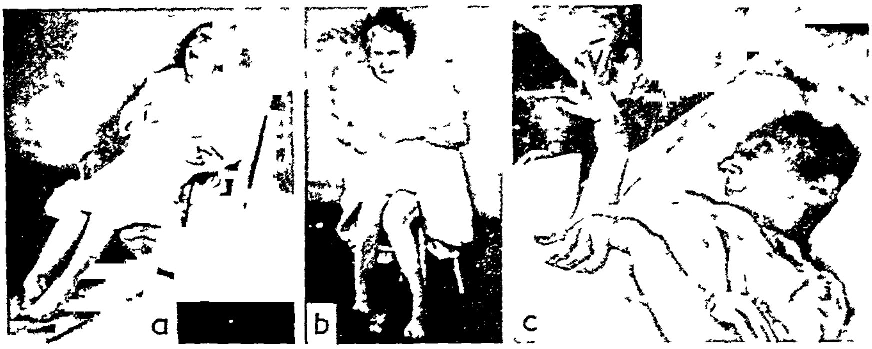

Fig 6—Terminal stages of paralysis agitans, to show flexion dystonia

The lesion of the globus pallidus is described by Bielschowsky (1922), and in detail by Foix and Nicolesco (1923, 1925), who called it "paravascular degeneration" It was regarded as the first stage of a change that later leads to more evident loss of tissue elements (*etat precrible*), and later still to pericapillary destruction of tissue (*etat criblé*) It should be emphasised, however, that in paralysis agitans with paravascular degeneration no evidence of change in the walls of blood-vessels can usually be found If siderosis is present it must be an independent abnormality, for it can be severe in degree without producing paravascular degeneration The pattern of tissue damage reflects some peculiarity in the permeability of the smallest blood-vessels in this area, and is common in the earliest stage of some of the metabolic diseases affecting the basal ganglia

When *atherosclerosis* has affected the vessels of the basal ganglia, lesions of the putamen are more obvious than those of the globus pallidus Lacunes of softening appear in the putamen surrounded by foci of *etat crible* The clinical state is then most commonly that of pseudobulbar paralysis, with or without damage to the internal capsule and cerebral white matter In 2 of our cases with typical parkinsonian tremor and attitude, mild *crible* lesions were limited to the internal part of the putamen and outer globus pallidus Only associated atherosclerosis of the arterioles, and the presence of the *crible* state in the putamen, then differentiate arteriosclerotic parkinsonism of this type from what we would call true paralysis agitans The pericapillary degeneration itself is more severe but otherwise closely resembles "paravascular degeneration" There may be small foci of similar paravascular degeneration in the substantia nigra, but these are not necessarily present Paravascular degeneration, I believe, is not directly the result of atherosclerosis but is worsened in extent and degree by its presence The evidence for this will presented elsewhere The occasional cell inclusions that have been noted by Lewy (1923), Hassler (1937a), and Greenfield and Bosanquet (1953) in the substantia nigra have been found in the Boston City Hospital in all types of case I am not convinced that they are a primary or specific change

In my monograph in 1945 I made a sharp distinction between true paralysis agitans and arteriosclerotic parkinsonism With greater experience I have to admit that this distinction is not absolute There is every degree of transition At one end of the scale one can recognise a slowly progressive gentle tremor at rest, with mild rigidity, that may begin in the fifth decade, with slight paravascular changes limited to the globus pallidus At the other extreme the marked rigidity and fixed hemiplegic posture of the pseudobulbar type is related to the "lacunar" state, with multiple small infarcts of the putamen Between lies every conceivable relative proportion of tremor and rigidity Thus arteriosclerotic parkinsonism may begin with rigidity, tonic grasp, and tonic foot response, with very little tremor In this type the putamen appears to be invariably damaged, and is perhaps first affected Yet rigidity can also occur with pallidal lesions A patient of mine, an 81-year-old man who had first developed typical parkinsonian rigidity and tremor twenty-one days before death, presented recent partial infarction (circumscribed pallor) of the globus pallidus on both sides There was no change in the substantia nigra Lhermitte and Cornil (1921a) cited a similar case

The symptomatology of paralysis agitans consists of the well-known tremor and rigidity In the tremor the opposed thumb beats against the first finger, and is associated with tremor of the lips and tongue before other parts The soft yielding plastic rigidity of paralysis agitans appears first in the flexors of the upper limbs, and is associated with delay in initiation of movement, though the relative degrees of bradykinesia and objective rigidity are greatly variable Seldom is it emphasised that in typical paralysis agitans the rigidity is invariably associated with change in posture, its preponderance in the flexor groups gradually leading to the stooped posture with flexed limbs, fixed facies with staring eyes, and open mouth, by which parkinsonism can be recognised in a photograph It is important also to emphasise that in the natural course of the disease the postural change gradually worsens until in a terminal stage all the limbs are drawn into a fixed attitude of general flexion (fig 6) The wrists are then strongly flexed and pronated, the fingers are extended, and the ankles are plantar flexed Attempted displacement of any part away from this attitude then meets a mounting resistance, and the part rapidly returns to its resting attitude This terminal loss of plasticity is associated with great lessening or loss of the tremor Speech is also lost or reduced to a mumble

Studies of arteriosclerotic parkinsonism indicate that the coarser the lesions of the external segment of the globus pallidus the more rapid has been the development of dystonia, with correspondingly less evident tremor If the putamen is involved tremor may not occur, and the rigidity is then not only more intense but also involves the extensors of the lower limbs and the flexors of the upper limbs (hemiplegic distribution) The pattern of rigidity as well as its intensity reflect the more lateral and lacunar lesions

In *postencephalitic parkinsonism*, though the same tremor may be present, it is more often damped or abolished by an intense asymmetrical rigidity The rigidity passes more rapidly into the fixed attitudes of dystonia, leading to torticollis, scoliosis, and grotesque postures of the limbs On the side on which dystonia was absent or delayed in appearance, the tremor tends to be more violent and more extensive than in paralysis agitans In addition various forced movements and compulsions, of which the oculogyric crises are the best known, are peculiar to the postencephalitic state Like others, we at Boston have found a severe destruction of the substantia nigra in all cases, but we have also found a diffuse pallor of the fibre systems of the globus pallidus Obvious nerve-cell changes in the globus pallidus or striatum are seldom found, but small foci of lesser change are common More important, we have often found loss of the small thinly medullated fibres entering the external putamen from the external capsule, and the external lamina of the globus pallidus from the internal capsule, with or without paucity of striopallidal fibres There is corresponding gliosis This inconspicuous change is of great significance in relation to the prominence of symptoms of corticostriate and corticopallidal disorder, and I shall return to it in my second lecture In the acute stages of lethargic encephalitis destruction of the substantia nigra was commonly found in patients without parkinsonism (Meyer 1923, Holzer 1926) If 75% of the substantia nigra is destroyed in most cases of postencephalitic parkinsonism, this still fails to account for the varied and complex disorders of motor function of that disease, and their delay in appearance Still less is the similar symptomatology in paralysis agitans explained by the inconstant meagre changes in the substantia nigra and locus cœruleus in that disease

Focal Lesions of the Basal Ganglia

The natural history of diseases that commonly affect the basal ganglia of the brain has been outlined in order to draw attention to their general tendency to produce involuntary movements that progress slowly to states of rigid maintenance of abnormal attitude We shall now turn to the effects of acute destructive lesions, which, by contrast, produce striking disorders of attitude from their beginning

Necrosis of the Striatum (Putamen and Caudate Nuclei)

Bilateral symmetrical necrosis of the caudate nucleus and putamen has been found in conditions such as death from status epilepticus in children, when anoxic damage to small vessels is presumably the primary mechanism

Marinesco and Draganesco (1929) describe this condition after convulsions in a child aged $4^1/_2$ years, who survived to the age of 6 There was patchy laminar necrosis of the cerebral cortex, and only mild degenerative changes were found in the globus pallidus Until death the child lay in an unresponsive state without making purposeful movements There was complete absence of speech, and swallowing was difficult At first the limbs were extremely rigid in flexion, but they would extend with changes in posture, and athetoid movements were present Later rigidity was less evident when the child lay on a surface, though all the limbs were semiflexed, the wrists pronated, the fingers flexed, the ankles extended, and the toes plantar flexed When the child was suspended in air, all the limbs became intensely rigid, the arms flexed, the hands clenched, the lower limbs extended, the ankles inverted, and the toes flexed This posture would persist as long as the child was suspended This phenomenon of the appearance of rigidity when the patient is lifted from a surface is commonly called ‘ the Foerster syndrome ” Foerster (1909), however, described only the atonic type of cerebrocerebellar diplegia, and the extension of the limbs when suspended appears to have been first described by Batten and von Wyss (1915)

Hawke and Donohue (1951) described, in a 13-year-old child, a similar complete bilateral necrosis of the whole corpus striatum, caudate, putamen, and globus pallidus, which occurred during a febrile illness complicating otitis media, without any known episode of anoxia During two months of survival the child did not speak or respond to commands The eyes would follow the movements of another person, and even moving objects late in the survival period The muscles were at first hypotonic, but they gradually became stiff in flexion, particularly during passive movement Occasional myoclonic twitching of muscles was observed The remarkable phenomenon of rigidity when suspended is not mentioned by these workers Similar cases have been reported by Verhaart (1938)

Complete clinical and anatomical studies of cases of unilateral destruction of the putamen and caudate nucleus are equally rare I cannot here discuss in detail such a case in the collection of my colleague Dr Yakovlev, suffice it to say that for the last ten years, before death at the age of 25, the patient had presented a dystonic contracture of the right arm in flexion and the right leg in extension, with consistent flexor plantar responses There was a severe spastic dysarthria Mobile athetoid spasm of the hand had preceded the dystonic attitude of extended fingers, and flexed wrist and elbow Steck (1921) reported a similar case, though the dystonia was not fully described

When bilateral partial cystic infarction of the putamen has occurred without damage to the internal capsule, the clinical condition has been that of pseudobulbar palsy (as first described by Richard Bright 1831) The pseudobulbar state resulting from Wilson's disease, and the condition resulting from manganese poisoning (Peñalver 1955, Berry and Bidwai 1959), have obvious features in common

Necrosis of the Globus Pallidus

One of the most striking lesions of the basal ganglia is the symmetrical necrosis of the globus pallidus found in patients who have had an episode of coma as a result of inhalation of coal gas, or carbon monoxide, or occasionally nitrous oxide, and rarely in those who have had other types of asphyxic anoxia It can also follow intoxication by carbon disulphide (Richter 1945)

The patient commonly recovers from the initial coma, and he may be discharged from hospital apparently completely relieved, or with only slight mental confusion After one to three weeks, he may then relapse into coma a second time, and succumb in that state Most often the delayed relapse presents as the onset of an akinetic mute state, with rigidity In other cases the relapse takes the form of renewed confusion in which elements of visual agnosia and catatonic postures are prominent, presumably resulting from lesions of cerebral white matter In a few cases a mild parkinsonian rigidity makes its appearance within six weeks of recovery from the initial coma

I need not here discuss the many interesting aspects of the neuropathology, which has recently been reviewed by Meyer (1958), whose earlier papers are among the most authoritative Widespread patchy areas of cortical ischæmic damage may occur Their presence is to be suspected whenever mental confusion is persistent The lesion that concerns us here more particularly is necrosis of the globus pallidus It is commonly found when death has occurred soon after exposure, without recovery from coma, and it is usually bilateral and approximately symmetrical Some part of the globus pallidus, usually the most anterior part of the internal segment, is the site of a hæmorrhagic softening, commonly occupying only a small part (10 to 20%) of the nucleus There is usually no incrustation of the vessels in this early stage The necrosis is clearly secondary to vascular damage

Where death has occurred after a delayed relapse, with onset of akinesia and rigidity, the infarct is usually larger, and it may involve the external segment or even portions of the putamen An associated lesion of the substantia nigra has been reported (Hiller 1924) but is very rarely found In a few such cases evidence of cortical damage is very slight, and white-matter lesions have been absent

Of 2 such cases followed closely in life, 1 showed an unvarying akinetic state for six months

This 58-year-old man was found in coma in a small unven-

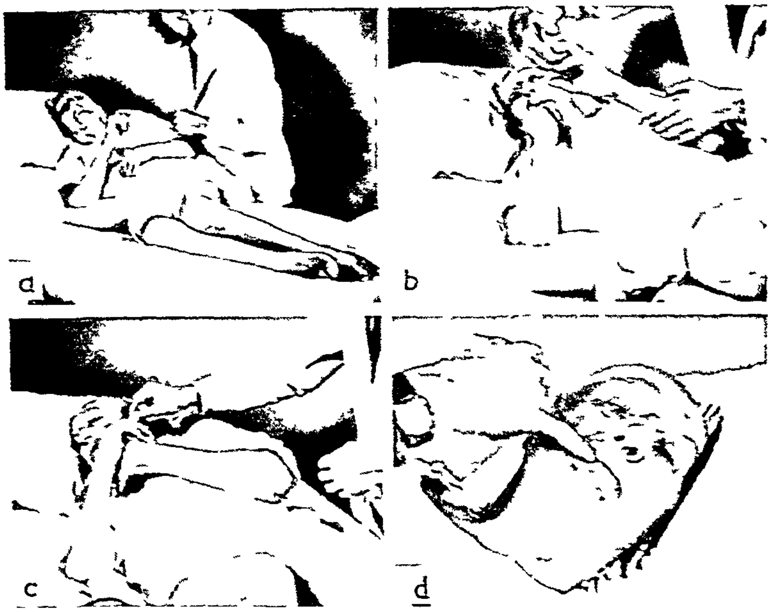

Fig. 7—Carbon-monoxide poisoning: (a) to show the flexed akinetic mute state, (b) the absence of grasp response, (c) the small response to pinprick on the face, and (d) tight closure of the mouth when lips were touched.

tilated hut, with a burnt-out brazier fire, without chimney. He lay unreflexic for a day but then made a rapid recovery. Eight days later he was able to speak, to read a newspaper, and to travel from Florida to Boston. On the ninth day he was found to be very drowsy, and he rapidly lapsed into an unresponsive state, with arms and legs moderately rigid in semiflexion. His eyes were open and they occasionally followed the movements of the examiner. He slowly scratched the face if pricked with a pin, but he gave no other reaction. The deep-tendon reflexes were present but not increased. Both plantar responses were extensor. The face was expressionless. Swallowing was possible only if fluid was introduced far back into the mouth. Any attempt to open the lips or mouth passively met increasing resistance. The limbs were held continuously in a semiflexed posture, the wrists were flexed, and the ankles extended. Because of mild plastic rigidity, they resisted attempts to extend them passively. The fingers were extended and were not used, except for a feeble brushing movement at a noxious stimulus to the face. There was no grasp response to a light stimulus, but, occasionally, after heavy stroking, a feeble grasp was obtained. Such responses are illustrated in fig. 7 from another patient who survived in an identical state for many months but in whom necropsy was not obtained.

In the first patient examination of the brain showed the characteristic lesions of the globus pallidus. There was no lesion of the substantia nigra, or thalamus, or other part of the extrapyramidal system. The cortex was virtually unaffected, but some patchy lesions in the frontal white matter of the orbital cortex were found on both sides, with a smaller lesion in the deep parietotemporal white matter. In this case vascular lesions of two different stages were apparent, supporting the hypothesis that the lesion had in fact enlarged after the latent interval. The occluded vessels were calcified in the area of more recent extension of softening.

In general small pallidal lesions have not been associated with extrapyramidal signs other than slowness in initiation of movement. The most intense akinesia and rigidity has followed large lesions. Where rigidity in flexion has followed after a long interval, I suspect that the lesion has enlarged because of delayed vascular changes, even after as long as seven years (Alexander 1942), and even forty-nine years in the report of Yakovlev (1944).

Focal Subthalamic Lesions

Discussion of the involuntary movements of *hemiballismus* resulting from lesions in the subthalamic nucleus will have to be omitted, except to emphasise that the characteristic movement involves a rotary element at proximal joints. This rotary element also appears in the posthemiplegic chorea associated with some types of thalamic lesion, and in the “ midbrain ” tremor so well described by Holmes (1904). When progressive lesions affect the general region of the midbrain tegmentum, rigid extension and internal rotation of all limbs eventually appears. This is the most common type of “ decerebrate rigidity ” encountered in man. Cathala (1922) has described a unilateral example resulting from tumour of the tectal region.

General Conclusions

In this necessarily abbreviated account of the general aspects of the symptomatology of diseases of the basal ganglia I have emphasised the diffuse nature of the pathology of such diseases, and their general tendency to produce involuntary movements that gradually make transition to abnormal postures. These two features are of special importance, for one of the most baffling aspects of these syndromes has been the inability of the physiologist to reproduce them by surgical or electrolytic lesions. It has not been appreciated that focal necrotic lesions of the putamen and globus pallidus can in man produce the terminal states that are seldom reached by degenerative diseases of the same structures. In particular I would stress the akinetic mute state of general flexion of all limbs, with pronated wrists and extended fingers, that is characteristic of severe destruction of the globus pallidus (“ pallidal syndrome ”). In milder degrees there is associated tremor of parkinsonian type. In contrast the more rigid flexion of upper limbs and extension of the lower limbs, greatly intensified by suspending the patient free of contact with body surface, is characteristic of destruction of the putamen and caudate nucleus (“ striatal syndrome ”). Lesser degrees of this disorder are characterised by athetosis and “ mobile spasm ”. With these two basic postural changes in mind their physiological meaning, and the significance of the disorders of movement that are associated with them, may be approached.

(*The references will appear at the end of the second lecture.*)

“ The more efficient society becomes at rapidly modifying our environment and our ways of life, the more unpredictable are the responses of man to the new conditions of his own making. In order to meet its professional responsibilities, medicine must add to its preoccupation with disease the study of the responses of normal man to the rapidly changing environment. It must supplement the knowledge of pathology with a new science which might be called biological technology. At least, this is the conviction which has led me, a bacteriologist, to focus my thoughts increasingly on the factors, external and internal, which condition the response of man to the microbes which are an ubiquitous part of his environment.”

IN a review of the possible causes of sudden death in infancy, Barrett (1954) suggested that of such cases "perhaps the majority are due to the inhalation of regurgitated food into the lungs" The inhaled food might not cause death by directly obstructing the air-passages an amount of milk too small to cause immediate asphyxia might excite an inflammatory reaction accompanied by pulmonary œdema, or the absorption of undue amounts of milk derivatives into the blood-stream might cause a state of shock

Such effects of inhaled food or vomit, if they occur, might be due either to an inherent toxicity of the inhaled material when it enters the body by this abnormal route, or to an anaphylactic type of reaction resulting from antigenic sensitisation

We present some experimental evidence which suggests that the second, but not the first, of these two mechanisms is indeed a possible cause of sudden death in infancy The hypothesis is that some infants may be in a hypersensitive state from the development of antibodies to the proteins of milk absorbed from the alimentary tract Infants often regurgitate stomach contents while asleep, and should some of this material be aspirated into the respiratory tract of an infant which has become hypersensitive, the result might be fatal

There is no doubt that most infants fed on cow's milk develop antibodies to the proteins of the milk Gunther, Aschaffenburg, Matthews, Parish, and Coombs (1960) using a sensitive technique—the coated tanned red-cell test of Boyden (1951)—showed milk antibodies in normal children aged 7–97 weeks in a titre up to 1000 with a modal distribution around a titre of 64

There thus seems to be ample evidence that the majority of infants are immunised to some degree or other to the proteins of cow's milk, and the possibility exists that these or other types of antibody may sensitise the tissues of the infants Anderson and Schloss (1923) showed that in infants with some types of nutritional disorders, milk proteins were absorbed via the alimentary tract and that subsequently precipitins to milk protein could be shown in the infants' sera, and these antibodies could sensitise guineapigs passively to anaphylaxis According to Clein (1958), up to 6% of infants during the first few months of their lives are allergic to cow's milk

Parish, Barrett, and Coombs (1960) showed that administration of milk over the glottis into the larynx of unsensitised conscious guineapigs was for all intents and purposes without clinical effect On the other hand, a small amount of milk dropped into the larynx of sensitised guineapigs resulted in a characteristic anaphylactic reaction often leading to death The reaction itself and the pathological findings in such animals were those of frank anaphylaxis and did not resemble those seen in human cot-death cases If, however, the guineapigs were lightly anæsthetised—an experimental condition used to simulate the condition of the sleeping child—milk introduced into the larynx had quite a different effect In the unsensitised guineapigs there was no untoward effect, and even in the sensitised animals there was a complete absence of the usual features of anaphylaxis seen in a conscious animal Very soon after introducing the milk preparations into the larynx of an anæsthetised sensitised guineapig, the animal stopped breathing without any signs of struggle Death sometimes occurred immediately, but the majority of animals took deep breaths at 10–30-second intervals for a variable period Death was preceded by a short period of more rapid breathing, each respiratory effort being shallower than the preceding one, until, with a final nose-twitching, the animal died Others lingered for 20–60 minutes before death took place, or normal respiration was gradually resumed This sequence of events became recognised as characteristic, and was reproducible on challenge of all the anæsthetised sensitised animals The pathological findings in the animals which died resembled those in human cot-death cases

In the present paper we have tried to relate our experimental results more directly to the condition in man (1) Sera from actual cases of cot death have been examined for their level of milk antibodies, as shown by the coated tanned red-cell test, in order to see if the distribution of levels is higher, as would be expected, than in randomly selected infants of comparable age (2) To test our hypothesis that the aspirated milk proteins originate as a regurgitation from the stomach, experiments have been performed on anæsthetised sensitised guineapigs in which the stomach contents recovered from cases of cot death were introduced into the respiratory tract Only stomach contents from infants known to have been bottle-fed at the time of death were used (3) Experiments have been performed to see if the individual milk proteins can produce a lethal effect (4) The pathological findings in guineapigs killed in this way are compared with those in cases of human cot death

Materials and Methods

These have been described in detail in two previous papers (Parish et al 1960, Gunther et al 1960)

Milk and Milk Proteins

As National dried milk powder is the product given to the majority of bottle-fed infants, it was employed as the source of milk proteins in our previous studies In the present work this product was again used as the sensitising antigen and the soluble proteins of the reconstituted powder used to coat the tannic-acid-treated *red cells in the serological tests for milk* antibodies

The isolated proteins of cow's milk—namely, casein, α-lactalbumin, and β-lactoglobulin—were prepared as described by Gunther et al (1960) and were kindly supplied by Dr R Aschaffenburg

Testing Sera for Antibodies

The method was basically the coated tanned red-cell technique of Boyden modified as described by Gunther et al (1960) The tanned red-cells were coated by exposing them to a 0 5% solution of protein antigen

Sensitisation of Guineapigs and Challenge

The guineapigs each received one intraperitoneal injection

---

* Elmore Medical Research Fellow, University of Cambridge

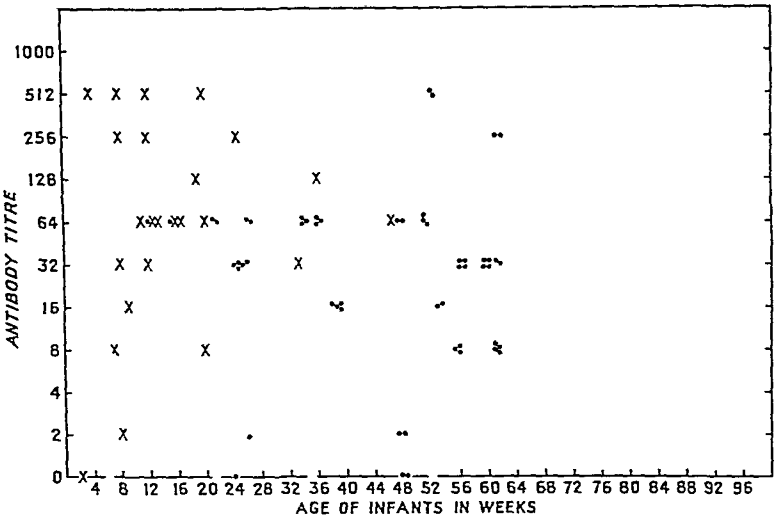

Fig 1—Titres of serum-antibody to cow's milk proteins at various ages in 24 ' cot-death ' cases (X) and in 286 normal infants (●)

A strict comparison of the two categories is not possible for the reasons stated in the test

of 1 ml reconstituted milk powder 2% w/v The inoculum consisted of the soluble and insoluble material

In experiments with human stomach-contents the animals were challenged on the 18th day after injection In experiments with milk proteins they were challenged on the 69th day

Anæsthesia

Pentobarbitone (' Nembutal ') was used as the anæsthetic in a dose of 0 01 ml per 20 g body-weight given intraperitoneally The depth of anæsthesia was such that the corneal reflex was very weak or just absent and the pedal reflex still present This was usually achieved in 15 minutes after injecting the pentobarbitone

Challenge via the respiratory tract—This was designed to mimic, as closely as possible, the accidental inhalation of regurgitated stomach contents by the sleeping infant The method has been fully described and illustrated by Parish et al (1960) With the aid of a gag and an illuminated nasal speculum, the mouth was opened and the entrance to the pharynx exposed While the tongue was depressed by a thin metal spatula, the milk or other challenging antigen was introduced over the glottis from a specially shaped blunt needle attached to a syringe When the animal inspired through the mouth it was possible to see the epiglottis which was the guide to the site of injection With practice it was possible to deposit the milk drop by drop over the glottis so that it was inhaled even when the larynx was invisible to the operator This procedure caused the minimum amount of damage to the respiratory tract

Experimental Study

Serum Antibody Levels

Using coated tanned red cells Gunther et al (1960) tested the sera of 286 normal children aged 7–97 weeks (fig 1) Nearly all the sera contained measurable antibody to cow's milk proteins In distribution the mode fell around a titre of 64 Approximately 4% had a titre of 256, 1% a titre of 512, and one serum had a titre of 1000 The plot of serum titre against the age in weeks of the child is shown in fig 1

We have now tested sera from 24 cases of cot death for the titre of antibodies to cow's milk Only those cases of sudden death were included which, on the pathologist's report, could be considered as " cot-death " cases These infants were known to have been bottle-fed at the time of death, and milk was found in their stomachs at post mortem

The serum titres of antibody to cow's milk in the cot-death cases are also shown in fig 1 where the distribution can be seen in relation to that found in normal infants

The number of cases available so far is not sufficient for a final assessment, nor is the mode of selection in the two categories appropriate for a strict comparison between the serum levels in normal infants and in the cot-death cases In the first place approximately 32% of the normal infants were known to be mainly breast-fed at 6 weeks of age, while the cot-death cases studied were all bottle-fed at the time of death Moreover, the blood from normal infants was collected under ideal conditions and the sera frozen to −15°C within 5 hours of bleeding, while the blood from cot-death cases was obtained post mortem and often had considerable precipitates which had to be centrifuged out before testing However the high titres found in the sera of the majority of cot-death cases are in keeping with the possibility that, had these infants aspirated milk into their respiratory tracts, a lethal hypersensitivity reaction, as seen experimentally in guineapigs, might have occurred

We are not suggesting that the level of serum antibody is necessarily a measure of the degree of sensitivity, although for the type of anaphylactic reaction envisaged this cannot be excluded It does indicate, however, that the infants have received a considerable antigenic stimulation with cow's milk and are, for this reason, potentially sensitised to these proteins

Effect of Stomach Contents on Sensitised Guineapigs

In our previous experiments (Parish et al 1960) National dried milk was used as the material for challenge In the present paper we report a similar experiment but the material used was stomach contents from actual cot-death cases in which the infant's last feed had been from the bottle This was used because, in the hypothesis we put forward, we believe regurgitated stomach contents are the source of the aspirated material initiating the lethal reaction

In this experiment both sensitised and unsensitised (control) guineapigs were lightly anæsthetised with an intraperitoneal injection of pentobarbitone Approximately 15 minutes later, when the desired state of anæsthesia had been reached, 0 25 ml of a 1/2 dilution of stomach contents (0 125 ml of the original contents) was introduced into the larynx Stomach contents from 4 cases of cot death were used The tenaciousness of this material necessitated its dilution with an equal volume of saline to avoid mechanical obstruction of the respiratory tract of the guineapig, which is, of course, much narrower than that of the human infant The stomach contents were obtained from dead infants aged 2, 4, 8, and 22 weeks The larger lumps found in the stomach of the oldest child were first broken down in a Griffith grinder

TABLE I—CLINICAL EFFECTS OF INHALING STOMACH CONTENTS FROM HUMAN COT-DEATH CASES BY NORMAL AND BY PREVIOUSLY SENSITISED GUINEA-PIGS LIGHTLY ANÆSTHETISED TO SIMULATE SLEEP

Challenge with stomach contents of dead infant	Dose of diluted stomach contents	Sensitised guineapigs		Unsensitised guineapigs	
		Reactions	Deaths	Reactions	Deaths
A aged 2 weeks	0 25 ml	D D D D + + −	4/5	+ − − − −	0/5
B, aged 4 weeks	0 25 ml	D D D + + −	3/5	− − − − −	0/5
C, aged 8 weeks	0 25 ml	D D D D	4/4	− − − −	0/4
D aged 22 weeks	0 25 ml	D D D D − −	4/5	+ + − ∸ −	0/5

Scale of severity of clinical effects
D=death
+ + + =severe respiratory embarrassment just insufficient to be fatal
+ − =definite clinical disturbance but not severe
− =one or two signs of respiratory embarrassment but always mild
— =no response

In a review of the possible causes of sudden death in infancy, Barrett (1954) suggested that of such cases " perhaps the majority are due to the inhalation of regurgitated food into the lungs " The inhaled food might not cause death by directly obstructing the air-passages an amount of milk too small to cause immediate asphyxia might excite an inflammatory reaction accompanied by pulmonary œdema, or the absorption of undue amounts of milk derivatives into the blood-stream might cause a state of shock

Such effects of inhaled food or vomit, if they occur, might be due either to an inherent toxicity of the inhaled material when it enters the body by this abnormal route, or to an anaphylactic type of reaction resulting from antigenic sensitisation

We present some experimental evidence which suggests that the second, but not the first, of these two mechanisms is indeed a possible cause of sudden death in infancy The hypothesis is that some infants may be in a hypersensitive state from the development of antibodies to the proteins of milk absorbed from the alimentary tract Infants often regurgitate stomach contents while asleep, and should some of this material be aspirated into the respiratory tract of an infant which has become hypersensitive, the result might be fatal

There is no doubt that most infants fed on cow's milk develop antibodies to the proteins of the milk Gunther, Aschaffenburg, Matthews, Parish, and Coombs (1960) using a sensitive technique—the coated tanned red-cell test of Boyden (1951)—showed milk antibodies in normal children aged 7–97 weeks in a titre up to 1000 with a modal distribution around a titre of 64

There thus seems to be ample evidence that the majority of infants are immunised to some degree or other to the proteins of cow's milk, and the possibility exists that these or other types of antibody may sensitise the tissues of the infants Anderson and Schloss (1923) showed that in infants with some types of nutritional disorders, milk proteins were absorbed via the alimentary tract and that subsequently precipitins to milk protein could be shown in the infants' sera, and these antibodies could sensitise guineapigs passively to anaphylaxis According to Clein (1958), up to 6% of infants during the first few months of their lives are allergic to cow's milk

Parish, Barrett, and Coombs (1960) showed that administration of milk over the glottis into the larynx of unsensitised conscious guineapigs was for all intents and purposes without clinical effect On the other hand, a small amount of milk dropped into the larynx of sensitised guineapigs resulted in a characteristic anaphylactic reaction often leading to death The reaction itself and the pathological findings in such animals were those of frank anaphylaxis and did not resemble those seen in human cot-death cases If, however, the guineapigs were lightly anæsthetised—an experimental condition used to simulate the condition of the sleeping child—milk introduced into the larynx had quite a different effect In the unsensitised guineapigs there was no untoward effect, and even in the sensitised animals there was a complete absence of the usual features of anaphylaxis seen in a conscious animal Very soon after introducing the milk preparations into the larynx of an anæsthetised sensitised guineapig, the animal stopped breathing without any signs of struggle Death sometimes occurred immediately, but the majority of animals took deep breaths at 10–30-second intervals for a variable period Death was preceded by a short period of more rapid breathing, each respiratory effort being shallower than the preceding one, until, with a final nose-twitching, the animal died Others lingered for 20–60 minutes before death took place, or normal respiration was gradually resumed This sequence of events became recognised as characteristic, and was reproducible on challenge of all the anæsthetised sensitised animals *The pathological findings in the animals which died resembled those in human cot-death cases*

In the present paper we have tried to relate our experimental results more directly to the condition in man (1) Sera from actual cases of cot death have been examined for their level of milk antibodies, as shown by the coated tanned red-cell test, in order to see if the distribution of levels is higher, as would be expected, than in randomly selected infants of comparable age (2) To test our hypothesis that the aspirated milk proteins originate as a regurgitation from the stomach, experiments have been performed on anæsthetised sensitised guineapigs in which the stomach contents recovered from cases of cot death were introduced into the respiratory tract Only stomach contents from infants known to have been bottle-fed at the time of death were used (3) Experiments have been performed to see if the individual milk proteins can produce a lethal effect (4) The pathological findings in guineapigs killed in this way are compared with those in cases of human cot death

Materials and Methods

These have been described in detail in two previous papers (Parish et al *1960*, Gunther et al *1960*)

Milk and Milk Proteins

As National dried milk powder is the product given to the majority of bottle-fed infants, it was employed as the source of milk proteins in our previous studies In the present work this product was again used as the sensitising antigen and the soluble proteins of the reconstituted powder used to coat the tannic-acid-treated red cells in the serological tests for milk antibodies

The isolated proteins of cow's milk—namely, casein, α-lactalbumin, and β-lactoglobulin—were prepared as described by Gunther et al (1960) and were kindly supplied by Dr R Aschaffenburg

Testing Sera for Antibodies

The method was basically the coated tanned red-cell technique of Boyden modified as described by Gunther et al (1960) The tanned red-cells were coated by exposing them to a 0 5% solution of protein antigen

Sensitisation of Guineapigs and Challenge

The guineapigs each received one intraperitoneal injection

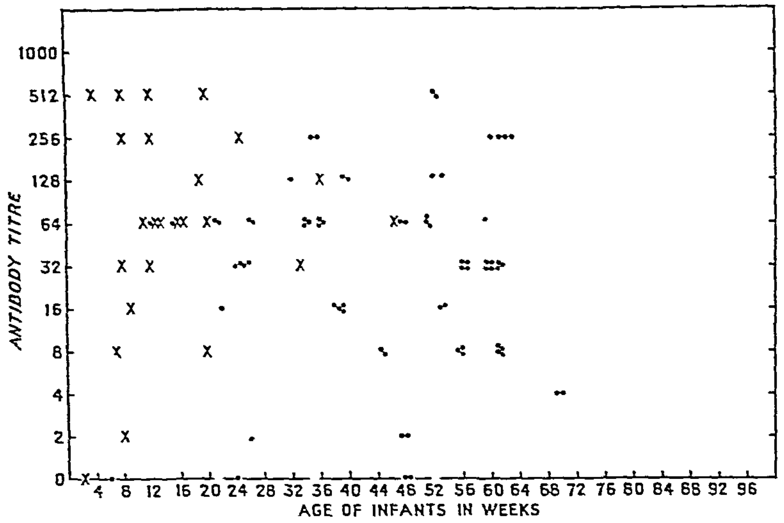

Fig 1—Titres of serum-antibody to cow's milk proteins at various ages in 24 'cot-death' cases (X) and in 286 normal infants (●)

A strict comparison of the two categories is not possible for the reasons stated in the test

of 1 ml reconstituted milk powder 2% w/v The inoculum consisted of the soluble and insoluble material

In experiments with human stomach-contents the animals were challenged on the 18th day after injection In experiments with milk proteins they were challenged on the 69th day

Anæsthesia

Pentobarbitone ('Nembutal') was used as the anæsthetic in a dose of 0 01 ml per 20 g body-weight given intraperitoneally The depth of anæsthesia was such that the corneal reflex was very weak or just absent and the pedal reflex still present This was usually achieved in 15 minutes after injecting the pentobarbitone

Challenge via the respiratory tract—This was designed to mimic, as closely as possible, the accidental inhalation of regurgitated stomach contents by the sleeping infant The method has been fully described and illustrated by Parish et al (1960) With the aid of a gag and an illuminated nasal speculum, the mouth was opened and the entrance to the pharynx exposed. While the tongue was depressed by a thin metal spatula, the milk or other challenging antigen was introduced over the glottis from a specially shaped blunt needle attached to a syringe When the animal inspired through the mouth it was possible to see the epiglottis which was the guide to the site of injection With practice it was possible to deposit the milk drop by drop over the glottis so that it was inhaled even when the larynx was invisible to the operator This procedure caused the minimum amount of damage to the respiratory tract.

Experimental Study

Serum Antibody Levels

Using coated tanned red cells Gunther et al (1960) tested the sera of 286 normal children aged 7–97 weeks (fig 1) Nearly all the sera contained measurable antibody to cow's milk proteins In distribution the mode fell around a titre of 64 Approximately 4% had a titre of 256, 1% a titre of 512, and one serum had a titre of 1000 The plot of serum titre against the age in weeks of the child is shown in fig 1

We have now tested sera from 24 cases of cot death for the titre of antibodies to cow's milk Only those cases of sudden death were included which on the pathologist's report, could be considered as "cot-death" cases These infants were known to have been bottle-fed at the time of death, and milk was found in their stomachs at post mortem

The serum titres of antibody to cow's milk in the cot-death cases are also shown in fig 1 where the distribution can be seen in relation to that found in normal infants

The number of cases available so far is not sufficient for a final assessment, nor is the mode of selection in the two categories appropriate for a strict comparison between the serum levels in normal infants and in the cot-death cases In the first place approximately 32% of the normal infants were known to be mainly breast-fed at 6 weeks of age, while the cot-death cases studied were all bottle-fed at the time of death Moreover, the blood from normal infants was collected under ideal conditions and the sera frozen to −15°C within 5 hours of bleeding, while the blood from cot-death cases was obtained post mortem and often had considerable precipitates which had to be centrifuged out before testing However the high titres found in the sera of the majority of cot-death cases are in keeping with the possibility that, had these infants aspirated milk into their respiratory tracts, a lethal hypersensitivity reaction, as seen experimentally in guinea-pigs, might have occurred

We are not suggesting that the level of serum antibody is necessarily a measure of the degree of sensitivity, although for the type of anaphylactic reaction envisaged this cannot be excluded It does indicate, however, that the infants have received a considerable antigenic stimulation with cow's milk and are, for this reason potentially sensitised to these proteins

Effect of Stomach Contents on Sensitised Guineapigs

In our previous experiments (Parish et al 1960) National dried milk was used as the material for challenge In the present paper we report a similar experiment but the material used was stomach contents from actual cot-death cases in which the infant's last feed had been from the bottle This was used because, in the hypothesis we put forward, we believe regurgitated stomach contents are the source of the aspirated material initiating the lethal reaction

In this experiment both sensitised and unsensitised (control) guineapigs were lightly anæsthetised with an intraperitoneal injection of pentobarbitone Approximately 15 minutes later, when the desired state of anæsthesia had been reached, 0 25 ml of a 1/2 dilution of stomach contents (0 125 ml of the original contents) was introduced into the larynx Stomach contents from 4 cases of cot death were used The tenaciousness of this material necessitated its dilution with an equal volume of saline to avoid mechanical obstruction of the respiratory tract of the guineapig, which is, of course, much narrower than that of the human infant The stomach contents were obtained from dead infants aged 2, 4, 8, and 22 weeks The larger lumps found in the stomach of the oldest child were first broken down in a Griffith grinder

TABLE I—CLINICAL EFFECTS OF INHALING STOMACH CONTENTS FROM HUMAN COT-DEATH CASES BY NORMAL AND BY PREVIOUSLY SENSITISED GUINEA-PIGS LIGHTLY ANÆSTHETISED TO SIMULATE SLEEP

D aged 22 weeks	0 25 ml.	D D D D ——	4/5	— — — — —	0 5

Scale of severity of clinical effects
D=death.
———=severe respiratory embarrassment just insufficient to be fatal
——=definite clinical disturbance but not severe.
—=one or two signs of respiratory embarrassment but always mild.
—=no response

In the unsensitised guineapigs no deaths, and in the great majority of cases no effects, were observed On the other hand most of the sensitised animals exhibited the syndrome already described and died silently, without any struggle, and in a very short time Three animals recovered after a protracted period during which there were long spells of apnœa interrupted only by occasional weak gasps One of the sensitised animals was apparently unaffected The results are summarised in table I

Effect of Milk Proteins on Sensitised Guineapigs

In our earlier report (Parish et al 1960) we recorded the level of milk antibodies and the clinical sensitivity to challenge with milk at 17, 38, 64, and 92 days after a single sensitising injection Although in some animals the level of serum-antibody appeared to fall with the passage of time the animals were as sensitive clinically to the aspiration of milk on the 92nd day as they were earlier We wished to see if a similar lethal reaction could be produced by the individual component proteins of cow's milk

The guineapigs were sensitised as before by injecting intraperitoneally 2% w/v reconstituted National dried milk in a dose of 1 ml On the 69th day they were challenged via the respiratory tract while under light anæsthesia with 0 25 ml of (*a*) the soluble proteins in 10% w/v reconstituted milk powder (approximately 1% soluble proteins), (*b*) 1% casein, (*c*) 1% α-lactalbumin, or (*d*) 1% β-lactoglobulin The day before challenge each animal was bled and the serum subsequently tested for antibodies to reconstituted dried milk, and to the component protein with which the guineapig was challenged

The results of the serological tests, and the clinical effects on challenge are recorded in table II Casein, as might be expected, proved to be as effective as whole milk in producing lethal reactions In one of the previous papers (Gunther et al 1960) similarly sensitised guineapigs tested 17 days after injection had antibodies to α-lactalbumin but none to β-lactoglobulin In the present experiment no antibodies could be shown to α-lactalbumin 69 days after injection Clinically only very mild reactions were produced on challenging with α-lactalbumin, but with β-lactoglobulin the reactions were as severe as with casein or whole milk

* Made up 10% w/v—approximately 1% soluble protein

† A 1% solution

Of thirty unsensitised (control) anæsthetised guineapigs challenged with soluble or insoluble milk preparations (Parish et al 1960) no reaction was observed in twenty six—one showed a very mild reaction and two a moderate reaction One animal died but on subsequent investigation its serum was shown to contain what appeared to be a naturally occurring antibody to cow's milk proteins to a titre of 16

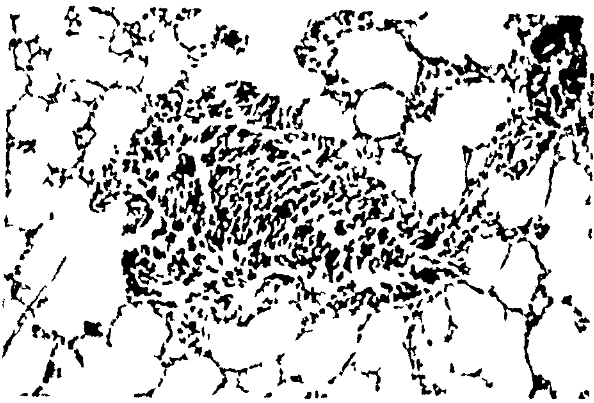

Fig 2—A bronchiole of anæsthetised sensitised guineapig which died soon after the introduction into its trachea of 0 25 ml of diluted (50%) stomach contents from a case of cot death (Hæmatoxylin and eosin ×120)

The bronchiole is so full of desquamated epithelial cells that in the photograph it is scarcely recognisable

We have thus shown that lethal reactions can be produced with casein and β-lactoglobulin On the other hand only mild reactions were obtained with α-lactalbumin However, further guineapigs will have to be tested at different periods after sensitisation before this protein can be considered less noxious than the other two

Pathological Findings in Sensitised Guineapigs

The histopathology of the lungs of sensitised guineapigs which died after inhalation, when anæsthetised, of total reconstituted dried milk, or its soluble or insoluble fractions, has already been described (Parish et al 1960) All the changes observed in the lungs of similarly sensitised guineapigs which died after the inhalation of casein or β-lactoglobulin closely resembled those in the earlier experiments In those sensitised animals challenged with β-lactoglobulin or casein, the chief features were generalised congestion with occasional areas of partial collapse, and serous exudate or œdematous transudate Cellular infiltration in the œdematous areas, or in the peribronchial, or periarteriolar connective tissue consisted chiefly of mononuclear cells Many of these were macrophages with variable numbers of lymphocytes and, in some animals, plasma-cells, but there were few polymorphonuclear cells A common finding was the desquamation of large numbers of single, intact, apparently normal, epithelial cells of the bronchial wall into the lumen of the small bronchioles

The histopathological changes in the lungs of sensitised anæsthetised guineapigs which had died as a result of inhaling small amounts of the stomach contents obtained from cot-death cases were similar to those observed in sensitised animals inhaling milk Generalised congestion was usual, but there was only an occasional small area of œdema and little cellular infiltration The infiltrating cells were chiefly macrophages, though there was an increased number of polymorphonuclear leucocytes—more than observed in animals challenged by milk The majority of the leucocytes were eosinophils, and in some preparations they were found also in the peribronchial connective tissue There was some evidence that the bronchioles and arterioles had undergone contraction, but further study of this feature is required Many of the medium-sized and smaller bronchioles contained large numbers of desquamated cells, sometimes these completely filled the lumen (fig 2) Bronchioles thus affected could be found in all the lung material, but the number varied from animal to animal The trachea was usually congested and in some cases infiltrated by eosinophils, the epithelium of the trachea was not desquamated

The unsensitised—i e , normal anæsthetised control guineapigs which had inhaled the stomach contents obtained from the same human subjects, and subsequently killed by an overdose of pentobarbitone—had different histopathological changes in their lungs There were large areas of partial collapse and œdema, or serous exudate, infiltrated with moderate numbers of macrophages and polymorphs of both the heterophil and eosinophil type All areas of the lung were congested and there was an occasional small hæmorrhage into the alveoli The epithelium of the majority of the bronchioles was intact, if it was not, the desquamation was in the form of sheets or strips of epithelium, and for the most part the individual cells were not detached from one another (fig 3)

The differences in degree of œdema and cellular infiltration between the unsensitised and sensitised guineapigs challenged with human stomach contents probably depend on the time that the irritant material remained in the living animal The majority of the sensitised animals died within 5 minutes, and all within 10 minutes, whereas the unsensitised animals were killed about 3 hours after challenge Previous experiments on normal animals revealed that the mode of killing by pentobarbitone did not cause changes of this type

The histopathological findings in sensitised guineapigs, dying after inhalation of milk proteins, are very similar to those described and illustrated in cot death by Barrett (1954) and Stewart (1957) The lungs of cot-death subjects are usually congested, and the engorgement of the capillaries is often accompanied by œdema, small hæmorrhages, foci of partial collapse, and an increase in the number of macrophages in the alveoli The walls of the bronchi are infiltrated by lymphocytes and plasma cells, sometimes there are also smaller numbers of polymorphonuclear leucocytes Desquamation of the bronchial epithelium is commonly seen (figs 4 and 5) and is often of the type described by Bodian and Heslop (1956), who thought that the presence within the bronchi of large numbers of individual desquamated cells embedded in mucus was characteristic of cot death, although it did not occur in every case

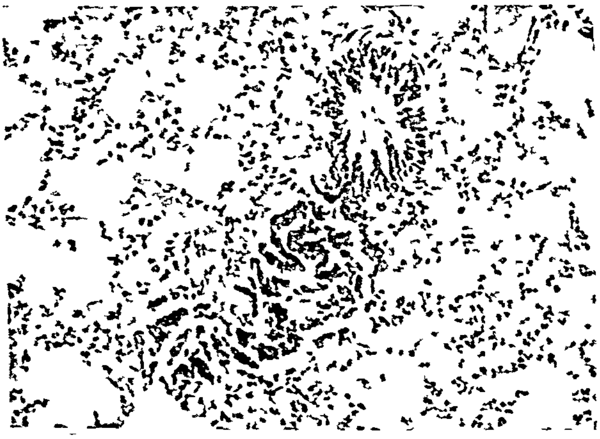

Fig 3—Bronchioles of an unsensitised guineapig which was killed 3 hours after receiving the same dose of the same stomach contents as fig 2. (H & E ×120)

The introduction of the stomach contents was without clinical effect The upper bronchiole is normal, the bronchiolar epithelium of guineapigs is normally more folded than that of man In the lower bronchiole, the lumen is occupied by strips of detached epithelium, but the appearance is different from that in fig 2

All of these histopathological features of cot death were also seen in the sensitised anæsthetised guineapigs which died after inhalation of small amounts of milk, or of stomach-contents containing milk Perhaps the most significant common finding was the presence of large numbers of individual intact epithelial cells in the lumina of the bronchioles The appearance was the same as that described by Bodian and Heslop (1956) except that in the guineapigs there was little if any mucus This difference may be due to an anatomical difference between man and guineapig, for there are very few mucous glands in the trachea and bronchi of the guineapig, and few goblet-cells in the epithelium Another difference between the human and the animal material is that in the guineapigs no desquamation of epithelium was observed in the trachea, though it occasionally occurred in the large bronchi Desquamation of epithelium is, however, a common postmortem change, which would be expected to be greater in the human than in the animal material because of the unavoidably longer interval between death and necropsy

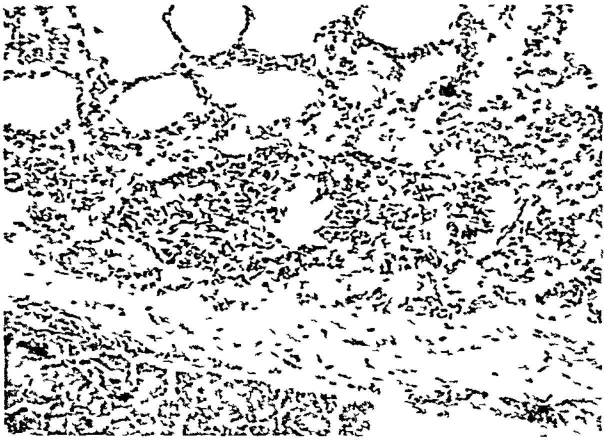

Fig 4—Bronchiole from case of cot death, showing lumen filled with desquamated epithelial cells (H & E. ×100)

Discussion

Sudden death of infants is by no means uncommon, and the Registrar General's data showed that in England and Wales in 1955, there were 1432 such deaths accounting for 20 5% of the 6993 deaths between the ages of 2 weeks and 2 years (Banks 1958)

The usual history is that of a baby dying in its sleep As a rule the babies are between 1 month and 6 months of age, though the incidence appears to be highest at about 3 months These deaths are attributed by many to a fulminating infection, although attempts to demonstrate a causal organism, either bacteria or virus, have been unsuccessful in most cases (Banks 1958)

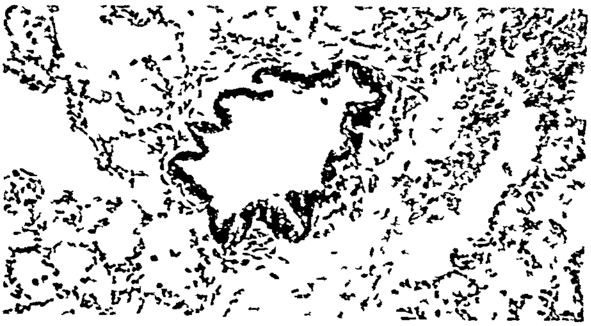

Fig 5—Bronchiole of infant believed to have died of suffocation (H & E. ×100)

The epithelium is intact except at the top left, where it has become partially detached Such detachment often occurs post mortem

The most common foreign proteins to which a baby is exposed are those of cow's milk, either as fresh milk, or as a preserved-milk product, which is also a constituent of proprietary preparations for infants It has previously been shown that babies may be sensitised to milk products (Anderson and Schloss 1923, Tallerman 1934) and this sensitivity may cause disease on contact with the milk antigen (Clein 1958) In the preliminary experiments, where examination was made of the sera of normal babies between 7 and 97 weeks of age for agglutinating antibodies to cow's milk, the large majority were found to have been " immunised " to some degree or other, and their tissues were probably sensitised by some form of antibody as a result of this immunisation (Gunther et al 1960) When, as in fig 1, the antibody titres to milk in the serum of babies believed to be typical cases of cot death are superimposed on those obtained from normal infants, it can be seen that in any age group the titres of the cot-death cases tend to be high when compared with the normal, indicating that a considerable degree of sensitivity could be present

In experiments performed on guineapigs (Parish et al 1960), which have been confirmed by the data presented in this paper, it was found that sensitised guineapigs in an anæsthetised state died after inhalation of milk proteins Death was not typical anaphylactic shock as observed in the conscious state, but the animal, without any struggle, stopped breathing either at once or after a brief episode of irregular respiration Animals not sensitised to milk could inhale up to 1 0 ml without significant effect The histopathological changes following challenge of the sensitised animals had much in common with those described in cases of cot death in infants

It has thus been demonstrated that sensitised animals, when unconscious, can be killed quickly, silently, and without trace of struggle by the inhalation of whole milk, or, at least, by two constituent proteins of milk, casein and β-lactoglobulin

It is well known that babies frequently regurgitate small quantities of food during sleep and often leave traces on the pillow In our hypothesis it is suggested that inhalation of regurgitated material can induce a lethal reaction, and that only small amounts need be aspirated The quantity aspirated by the infant may be of the order of 1 0 ml, on a comparison of the weights of the test guineapigs and cot-death subjects

We have been able to show that many babies have some antibody to cow's milk, and that guineapigs with a similar serum-antibody level can be killed quietly by aspiration of small quantities of milk

If the challenge agent in babies were food material from the stomach regurgitated during sleep, it had to be shown that this material retained its antigenic properties sufficiently to cause shock on contact with tissues sensitised to milk This was found to be so The stomach contents taken from 4 cases of cot death in which the infants were known to be bottle-fed, when inhaled in small amounts by lightly anæsthetised guineapigs sensitised to milk proteins, resulted in death, quietly and without struggle, in 15 of the 19 challenged animals The histopathological features were similar to those observed in cot death of infants An equal number of anæsthetised guineapigs, not sensitised to milk proteins, which had inhaled the same stomach-content material displayed no effects, or scarcely appreciable respiratory embarrassment, and there were no deaths

These experiments provide a model of a possible cause of cot death in infants If the serum level of antibody is a valid indication, the majority of babies are sensitised to some degree to cow's milk, and it is possible that a normal healthy baby may be put to bed, and, during its sleep regurgitate and inhale sufficient material to cause an antigen-antibody reaction in the sensitised tissue of the lungs, causing physiological and pathological changes resulting in the death of the infant

Further investigation of this problem is being undertaken An attempt is being made to prove that an antigen-antibody reaction has taken place in the lungs of such infants and that this reaction is of sufficient magnitude to cause death The nature or the degree of the sensitivity may be an important factor, for the number of babies that have a substantial titre of circulating antibodies to milk is large compared to the small number of cot-death cases, though another limiting factor may be the frequency with which aspiration occurs Nevertheless, the fact that babies do become sensitised to cow's milk proteins, and that inhalation of this material could conceivably be the cause of cot death in a young infant, should be another inducement to breast-feed young babies where practicable

Summary

Experimental evidence is presented to support the hypothesis that cot death in infants may be due to an anaphylactic type of reaction consequent on the inhalation of cow's milk proteins regurgitated from the stomach during sleep

Serological tests show that most infants fed on cow's milk develop antibodies to milk proteins

Experiments on anæsthetised guineapigs, sensitised to the proteins of cow's milk, show that many such animals die rapidly and without struggling when a small quantity (0 25 ml) of (*a*) cow's milk, (*b*) stomach contents from cases of " cot death ", (*c*) a 1% solution of casein, or (*d*) a 1% solution of β-lactoglobulin is introduced into the air passages

The histopathological changes in the lungs of the experimental animals resemble those found in cases of cot death

We wish to acknowledge the helpful discussion with the members of the steering committee and the scientific subcommittee of the " Enquiry into sudden death in infancy " under the respective chairmanships of Prof Leslie Banks and Sir Samuel Bedson and to thank this body and the Nuffield Foundation for a grant to cover the cost of animals used in these experiments They are most grateful to Dr H R M Johnson for his help in the collection of material from cot-death cases, and to Dr N R Butler and the pædiatric staff, University College Hospital, for their help in obtaining serum-samples

We thank Miss Brenda Disbrey and her staff for the painstaking work in the preparation of the histological material, Mr B W Gurner for drawing fig 1, and Mr S W Patman for taking the photographs

EFFECT OF PHENINDIONE AND BED REST ON BLOOD COAGULABILITY FOLLOWING A HIGH-FAT INTAKE

G. A. McDonald

LECTURER IN MEDICINE

H. W. Fullerton
M.A., M.D. Aberd., F.R.C.P., F.R.C.P.E.
REGIUS PROFESSOR OF MEDICINE

UNIVERSITY OF ABERDEEN

Recently we have shown that, when careful attention is paid to technique, the recalcified-plasma-clotting (R.P.C.) time is an accurate measure of in-vitro coagulability (McDonald and Fullerton 1958a). With further experience of this technique, in more than 200 samples of plasma, duplicate readings have given a mean difference of less than 3 seconds and a maximum difference of 7 seconds. A smooth non-traumatic venepuncture is essential. When this is achieved the mean difference between samples obtained from both arms in 15 patients was only 3.5 seconds, and in only 1 case was this difference greater than 8 seconds, which we take as the upper limit of experimental error (McDonald and Fullerton 1958a). Difficulty in venepuncture shortens the R.P.C. time. This is clearly shown in table I, which gives simultaneous R.P.C. times for both arms in 14 patients. The venepuncture was satisfactory in one arm; in the other it was unsatisfactory in that tissue trauma was produced, either inadvertently or by design. It is seen that the readings in the samples obtained by unsatisfactory venepuncture were consistently much shorter, the mean difference being 28.3 seconds.

TABLE I—SIMULTANEOUS R.P.C. TIMES (SEC.) IN BOTH ARMS: VENEPUNCTURE UNSATISFACTORY IN ONE ARM

Subject no.	Satisfactory arm	Unsatisfactory arm	Difference
1	103	75	28
2	124	110	14
3	130	115	15

13	131	116	15
14	115	93	22
Means	120.7	92.4	28.3

By this technique we have shown that (1) a high-fat breakfast containing 85 g. animal-fat (bacon, eggs, butter, tea with milk and sugar) resulted in a pronounced shortening of the R.P.C. times measured 3 and 4 hours after the meal (McDonald and Fullerton 1958a), (2) a similar reduction occurred after approximately the same amount of vegetable fat (McDonald and Fullerton 1958a), and (3) the effect of the high animal-fat breakfast was almost completely abolished by a moderate amount of physical activity (McDonald and Fullerton 1958b).

TABLE II—GROUP 1: RECENT CARDIAC INFARCTION, PHENINDIONE, BED REST

Subject no.	Fasting	3½ hr.	Difference

10	107	86	+21
Means	111.6	80.4	+31.2

Clinical Material and Methods

The methods used in these experiments and the details of the animal-fat breakfast (fat content, approximately 85 g.) have been described previously (McDonald and Fullerton 1958a). Four groups have been studied in this way:

Group 1.—10 inpatients at rest in bed, with recent cardiac infarction, treated with phenindione for periods varying from 4 to 18 days.

Group 2.—10 inpatients at rest in bed, with non-cardiac disorders, and not treated with phenindione.

Group 3.—10 outpatients with previous cardiac infarction who had had long-continued therapeutic doses of phenindione for periods varying between 12 and 45 months.

Group 4.—10 outpatients who had had a cardiac infarction and had received 1 mg. phenindione daily for periods ranging between 20 and 41 months. This group was drawn from the controls in the Medical Research Council (1959) trial of long-term anticoagulant administration after cardiac infarction.

The subjects in groups 3 and 4 were allowed to undertake some physical activity, in contrast to the subjects in groups 1 and 2 who were confined to bed both during and for several days before the experiment. They reached hospital by walking varying distances and by using public transport, and, after the high-fat breakfast had been taken, they were allowed to walk short distances from time to time in the ward corridors.

TABLE IV—GROUP 3: OLD CARDIAC INFARCTION, PHENINDIONE, AMBULANT

Subject no.	Fasting	3½ hr.	Difference
1	148	146	+2
2	123	125.5	−2.5
3	144	119.5	−5.5
4	187	174	+13
5	140	134	+6
6	188.5	176	+12.5
7	144.5	139	+5.5
8	127	134	−7
9	141	141.5	−0.5
10	130	131	−1
Means	147.3	145	+2.3

In groups 1 and 3 the one-stage "prothrombin-time" was maintained at 2 to 2½ times the control level, whereas in group 4 it was within the normal range. No patient in group 2 had a disorder likely to be associated with an abnormality of blood coagulation.

In addition to estimations of the R.P.C. times, the degree of lipæmia in each sample of plasma was measured by assessing the turbidity by a modification of the method described by Schwartz et al. (1952). Direct measurement of light transmittance was obtained with a Spekker photoelectric absorptio-

meter and expressed as the direct scale reading Glass cuvettes with a 2 mm light path and a blue filter (Ilford Spectrum Blue, 602) with maximum transmittance at 4700 Å were used

Results

The results are presented in tables II–V, which show the R P C times of all the subjects fasting and during the phase of lipæmia $3^1/_2$ hours after the meal It is seen that in subjects in groups 1 and 3 who were receiving therapeutic doses of phenindione, the fasting R P C times were slightly prolonged but the high-fat meal had no consistent effect on the R P C times during the lipæmic phase $3^1/_2$ hours after the meal In group 1 the greatest reduction was only 13 seconds and the mean reduction 3 6 seconds In group 3 the corresponding figures are 13 seconds and 2 3 seconds In group 4, receiving only 1 mg phenindione daily, the results were strikingly different In 8 of the 10 subjects the R P C times $3^1/_2$ hours after the high-fat meal were considerably shorter than the readings during fasting, and the mean reduction was 16 7 seconds This result is similar to that found in a group of 16 students who undertook little physical activity after the high-fat breakfast (mean reduction 23 8 seconds) (McDonald and Fullerton 1958b) In group 2 the mean reduction in R P C time $3^1/_2$ hours after the meal was still greater—31 2 seconds This is similar to the results found previously in 11 subjects confined to bed, in them the mean reduction in R P C time 3 hours after the high-fat breakfast was 39 seconds, and at 4 hours 35 seconds (McDonald and Fullerton 1958a)

Discussion

The results demonstrate that the ingestion of a high-fat breakfast by patients receiving therapeutic doses of phenindione (groups 1 and 3) does not produce the acceleration of the R P C time found in subjects not receiving this drug (groups 2 and 4) So far as we know this action of phenindione has not been demonstrated previously, its mechanism is obscure Clearly, however, it does not depend entirely upon an alteration in the degree of plasma turbidity during the lipæmic phase Table VI shows the mean percentage increase in turbidity $3^1/_2$ hours after the high-fat meal, and the mean decrease in the R P C time in the four groups of subjects In both groups of ambulant patients (groups 3 and 4) the increase in turbidity was less than in the patients at rest in bed (groups 1 and 2) But in group 1 the increase in turbidity was greater than in group 4, whereas the mean reduction in R P C time in group 1 was negligible and in group 4 it was considerable

A comparison of the findings in groups 2 and 4 has confirmed our previous impression that the reduction in R P C time is considerably greater in subjects confined to bed in hospital It seems that even the small amount of physical activity undertaken before and after the ingestion of the high-fat breakfast by the subjects observed as outpatients (group 4) offsets to some extent the increase in coagulability during the phase of lipæmia Further studies along these lines are at present in progress

The practical importance of the effect of phenindione which we have demonstrated is at present conjectural Because of the differences between the process of clotting in vitro and intravascular thrombosis, it is perhaps unwise to draw firm conclusions from results obtained with the R P C test and other laboratory tests of blood coagulability Nevertheless one essential feature common to clotting in vitro and intravascular thrombosis is fibrin formation, and it is not unreasonable to suggest that factors which can be shown to accelerate this process in vitro may also operate when intravascular thrombosis occurs

Many physicians treat patients with cardiac infarction with phenindione and by restricting their fat intake If shortening of the R P C time following a high-fat meal reflects increased coagulability in vivo and, therefore, an increased tendency to thrombus formation, there may be nothing to be gained by lowering the fat intake of patients receiving phenindione Moreover, it seems possible that the beneficial effect of phenindione in cardiac infarction may be due partly to its action in abolishing the increase in coagulability after high-fat meals

Summary

Shortening of the recalcified-plasma-clotting (R P C) time following the ingestion of a high-fat meal was *not* found in patients receiving therapeutic doses of phenindione

In subjects not receiving phenindione the shortening was greater in patients confined to bed than in those who were ambulant

We are grateful to Sister I M Cowie, ward 1, Aberdeen Royal Infirmary, for much help, and to the patients for their cooperation

MEDICAL TREATMENT OF MYCETOMA

W PETER COCKSHOTT

MYCETOMA is the name applied by H V Carter to a fungal infection prevalent in Southern India, which was locally termed Madura foot Although still often used for this low-grade fungal parasitism, the latter term is undesirable because it suggests an exclusive geographical and anatomical localisation

Mycetoma occurs predominantly in underdeveloped areas which have rudimentary medical facilities and often no auxiliary medical departments Thus we can hardly expect full mycological identification of the responsible organism in each case Ideally specific chemotherapy depends upon identification and culture of the organism, determination of its sensitivity to a range of drugs, and exhibition of the appropriate drug But even with the best of facilities culture is difficult and identification is a matter of experience and special training, whilst details of suitable drugs are at present mainly to be found in specialised journals, reports of their efficacy sometimes being difficult to evaluate Consequently an outlook of therapeutic nihilism has prevailed as far as mycetoma is concerned, and the treatment has almost invariably been surgical ablation of the affected tissues

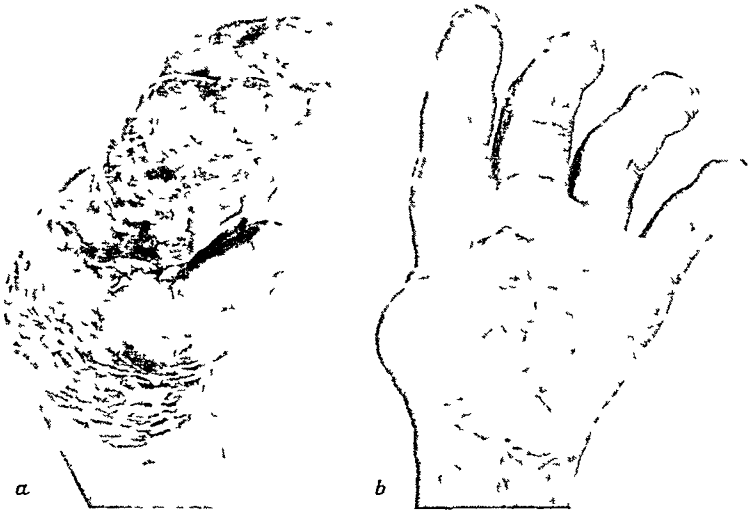

Fig 1—Left hand (*a*) on admission, and (*b*) 6 months later

Although not a killing disease, mycetoma causes a fair amount of morbidity and disablement—disablement which is little alleviated by amputation unless prostheses are available The effect upon a wage-earner and his family—the disease is primarily of active males—can well be disastrous

In these particular social and medical circumstances any drug advocated must have a wide range of effectiveness against the many possible causative organisms, and it must also be safe, cheap, and easy to administer A simple scheme of treatment, giving a satisfactory overall “ cure ” rate, is more likely to gain widespread acceptance than a more definitive but complex scheme, although a few cases may not respond to this shot-gun method Whatever the method there are still some fungi for which no specific therapy is yet known For those patients who fail to respond to chemotherapy amputation is still available

In Ibadan we have treated cases of mycetoma with a preliminary course of a wide-spectrum antibiotic, to eradicate the almost invariable secondary infection, combined with a long course of dapsone (diaminodiphenylsulphone), and, when feasible, with immobilisation of the affected part These patients were only admitted to hospital for a week or so until secondary infection had cleared, and they then continued to take dapsone, in a dosage of 100 mg b d , as outpatients After initial observation for a month they need only attend hospital every 3 months, and this regime may be continued for anything up to 2 years

Although surgery still plays a role in the treatment of mycetoma, it should not be invoked, except in special circumstances, until a reasonable course of medical treatment has been tried Orthopædic surgeons expect that bone and joint tubercle and leprosy require long-continued exhibition of drugs, and the same attitude should eventually prevail in the treatment of mycetoma Early surgery is probably justifiable in strictly localised forms of the disease, particularly the nodular superficial varieties caused by the black-grain *Madurella mycetomi*

Eight of a group of eighteen cases which we treated in Ibadan without radical surgery have responded, showing closure of sinuses, and clinical and radiographic improvement, and they have returned to their previous work We have been unable to follow all the patients because some defaulted or continued their course elsewhere—these have been assumed to be failures To know whether the “ clinical cure ” persists will require a longer follow-up, but at least these patients still have the use of their limbs

The dramatic response which can follow this treatment is shown by the following case-histories

Case 1—A 40-year-old Yoruba farmer came to hospital complaining of progressive swelling of the left hand, and of multiple discharging sinuses, which had been present for 3 years These had prevented him from working for the past year He was ashamed of his enormous foul-smelling hand, and kept it covered up and hidden within his gown

Multiple sinuses and ulcerated areas were present over both surfaces of the hand, and much foul discharge was exuding No grains could be seen The axillary lymph-glands on the same side were large and tender A radiograph of the hand disclosed extensive periosteal new bone enveloping the metacarpals and phalanges, and this was considered typical of a nocardial type of mycetoma, with secondary infection No fungal elements were observed in the pus, and only *Escherichia coli* was isolated on culture Biopsy of skin and subcutaneous tissues revealed a chronic inflammatory reaction, but no grains could be demonstrated Despite these negative bacteriological findings a definite clinical diagnosis of mycetoma was made

Tetracycline, 250 mg q i d was given for a week, and in addition dapsone 100 mg b d was started The patient continued on the drug for 2 years A month after starting treatment the hand had returned to more normal proportions and all the sinuses had healed Within 6 months of his first attendance the patient was again at work in the fields His hand is now completely healed, but the range of movement is limited partly by scarring but more so by degree of subluxation of his wrist which causes passive insufficiency of his flexors Now that the lesion is quiescent orthopædic procedures are envisaged to give a more useful hand (fig 1)

Case 2—A Yoruba tailor, aged 45, attended hospital because of progressive swelling of his left hand for 7 months and ulceration of his left axilla for the previous 3 months Because of this disability he had been unable to work The left hand was greatly swollen with multiple puckered sinuses exuding a thin serous discharge There were areas of ulceration in the axilla and on the chest wall (fig 2) A radiograph of the hand showed typical changes of nocardial-type diffuse mycetoma A biopsy specimen was taken but the tissue only revealed a chronic inflammatory reaction, and no grains A nocardia species was obtained from culture of the pus, but full identification was not possible as the strain died out *Esch coli* also grew from the pus

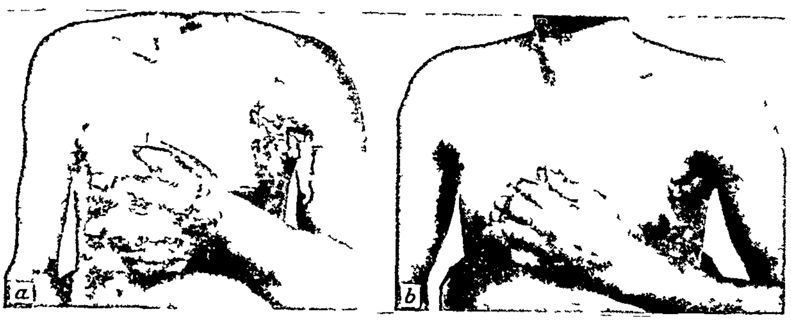

Fig 2—Appearance of case 2 (*a*) on admission, and (*b*) 7 months later

This clinical type of mycetoma, with early invasion of the thorax, is very serious and occasionally fatal, and justifies energetic treatment Penicillin 2 million units was given daily for 3 months, and at the same time dapsone 100 mg was given twice a day by mouth The ulceration in the axilla slowly healed during the first 3 months, and the sinuses of the hand had closed at the end of 6 months The patient now has an efficient hand and is again working as a tailor The course of dapsone lasted 2 years, during which time he showed no evidence of toxic reactions

Case 3 —A 20-year-old farmer came to the surgical outpatient department with a swollen discharging left foot Sinuses were present on the greatly swollen dorsum of the foot, and the inguinal glands on that side were enlarged and hard A radiograph revealed a destructive lesion of the second metatarsal, and some periosteal reaction near the head of this bone, which was reported as being probably due to mycetoma As no fungal elements could be recovered from the discharge, the lesion was considered tuberculous by the clinician and accordingly treated with *p*-aminosalicylic acid and isoniazid for 3 months without improvement

The patient was then admitted to hospital, and the foot was explored, with removal of the metatarsal and curetting of the sinuses The bone showed on section grains morphologically identical with *Nocardia braziliensis* The patient was given dapsone 100 mg b d for a period of 18 months 4 months after the operation the foot had completely healed and the patient had returned to work Surgery was probably not necessary in this case, but this form of local resection, with chemotherapeutic cover, may have led to more rapid healing

Discussion

Mycetoma is caused by a wide variety of organisms of different genera and species, and it presents by its very nature several features which tend to render it resistant to chemotherapy

Firstly, although the pathological processes may vary in degree of severity from the localised *M mycetomi* infections to the infiltrating lesions of *Allescheria boydii* and *Streptomyces pelletieri*, yet, in virtually all cases, the fungal elements occur within relatively avascular tissue resulting from scarring and local endarteritic changes

Secondly, once sinuses have developed pyogenic secondary organisms invade the lesion

Thirdly, the disease is caused by a variety of species each differing from the rest in its drug sensitivity, and even isolates of the same species may vary in their response from case to case

Because of the wide variety of causative organisms a single drug is unlikely to prove effective against all the possible organisms of mycetoma A further factor to be borne in mind is the geographical distribution of the different organisms A complete survey of this is impossible here, but, for example, in Southern Arabia and the Sudan the common organisms are *M mycetomi*, *Strep somaliensis* and *Strep pelletieri*, whereas in Western Nigeria *N brasiliensis*, *M mycetomi* and *All boydii* are probably the most frequent

The best therapeutic regime will probably vary according to the main species in any particular locality We do not suggest that our scheme of treatment is the only one, or even the best, but we have found it effective in salvaging limbs, and it is cheap Though blind therapy in a sense, it is suited to the conditions of practice where mycetoma is most frequent The basic principle of a course of antibiotics and prolonged drug administration, combined with immobilisation by sling or plaster-of-paris, seems to us rational Much that was written on the chemotherapy of this disease before 1950 is now merely of historical interest Some of the more recent developments have been reviewed by one of us (Cockshott 1957) and this paper can be consulted for more detailed references

Dapsone, though first synthesised in 1907, found no pharmacological application until 1937, when it was discovered to be effective in treating experimental streptococcal infections but it was too toxic for man in the dosage then being employed Dapsone possesses a degree of antituberculous activity, but its main use has been in the treatment of leprosy caused by acid-fast mycobacteria Ochoa found that dapsone was effective in vitro against the acid-fast nocardia, which causes some varieties of mycetoma, and systemic nocardiosis Encouraged by these tests he started treating mycetoma due to *N brasiliensis* with this drug, and the results were excellent (Ochoa 1955, Ochoa and Macatola 1955) Various other workers (Halde and Newstrand 1955, Mackinnon et al 1958) have shown that dapsone is effective in causing inhibition of growth of *M grisea*, *Strep maduræ*, and *Strep somaliensis*, as well as *N brasiliensis* The antifungal activity of this drug probably depends upon substrate competition for paraminobenzoic acid (Cockshott 1957)

Although the dosage of dapsone we have used may seem high, it appears to be safe We advise close observation during the first month to enable early detection of exfoliative dermatitis or hæmolytic anæmia in the occasional case One of our patients developed exfoliative dermatitis, and his therapy had to be discontinued

Summary

A plea is made for a more optimistic outlook in the treatment of mycetoma A regime based on a short course of wide-spectrum antibiotic and prolonged treatment with dapsone by mouth has been found effective In nearly half our cases, this treatment has avoided the need for amputation and enabled the patient to get back to work

We extend our thanks to the physicians and surgeons of University College Hospital, Ibadan, who have referred cases to us, and to Mr Frank Speed, of the medical illustration department, for the photographs

EVALUATION OF THROMBOTEST IN THE CONTROL OF ANTICOAGULANT THERAPY

H. LEMPERT
M.D., M.Sc. Manc., A.R.I.C.
CONSULTANT PATHOLOGIST IN CHARGE OF
THE ANTICOAGULANT THERAPY SERVICE

L. POLLER
M.D. Manc.
SENIOR REGISTRAR IN PATHOLOGY

From the Department of Clinical Pathology,
Manchester Royal Infirmary

CONTROL of anticoagulant therapy with coumarin or indanedione drugs has been based for many years on the one-stage prothrombin-time test of Quick (1935). Oral anticoagulant drugs undoubtedly lower the production of prothrombin, but the term "prothrombin-time" is somewhat of a misnomer, since it is factor VII which is mainly measured. Fortunately Quick's test is very sensitive to changes in factor VII activity. Drug dosage is so adjusted that prothrombin-times of $1\frac{1}{2}$–$2\frac{1}{2}$ times normal are obtained within a few days and maintained in this so-called therapeutic range. Quick (1938) demonstrated the hyperbolic relationship between prothrombin-times and prothrombin activity, normal prothrombin activity being 100%. Thus the "therapeutic range" is about 15–30% of normal if a saline extract of acetone-dried rabbit or human brain is used as thromboplastin reagent in the test.

During oral anticoagulant treatment hæmorrhages or further thromboses have sometimes been reported even where the greatest care has been taken to keep within the therapeutic range. In recent years it has been shown that, during treatment, factors involved in "intrinsic" blood-thromboplastin production—e.g., Christmas factor (factor IX), Prower-Stuart factor (factor X), and possibly others—are reduced. Quick's test does not register changes in Christmas factor because of the powerful tissue thromboplastin used.

Some workers are of the opinion that heparin-clotting-time methods give a better indication of impending complications (Soulier and le Bolloch 1951, Poller 1954) but, for technical reasons, such tests are not suited to the daily routine control of large numbers of patients on anticoagulants.

Owren (1959), in his 'Thrombotest' method, has modified the one-stage technique in order to produce a method capable of measuring "intrinsic" blood-thromboplastin factors as well as prothrombin and factor VII. The thrombotest reagent contains a thromboplastin of relatively weak activity, and it is claimed to possess some sensitivity to changes in Christmas-factor levels.

We made our present investigations to assess the value of the thrombotest method for the control of patients on phenindione ('Dindevan') therapy as compared with Quick's test and the prothrombin and proconvertin (P & P) test of Owren and Aas (1951). In view of the claims that thrombotest was sensitive to changes in blood-thromboplastin factors, it seemed essential to include a thromboplastin-generation test (T.G.T.).

Methods of Study

Forty-three inpatients undergoing phenindione anticoagulant therapy were studied. They were divided into two groups, A and B.

In group A, comprising thirty-one patients, dosage of the anticoagulant was based on the Quick prothrombin-time method, and observations were made of the effect on the P & P method, the T.G.T., and thrombotest. The clinical conditions included in this group were:

Coronary thrombosis	13
Pulmonary embolism	2
Venous thrombosis	2
Cerebral vascular disorders	3
Angina pectoris	8
Peripheral artery occlusion	3

In group B, which consisted of twelve patients, dosage was based on the result of thrombotest, and the observation was confined to the effect on the Quick prothrombin-time method and T.G.T. The cases included in this group were:

Coronary thrombosis	10
Pulmonary embolism	1
Prophylactic therapy	1

In group A, 415 blood specimens were tested during 530 days of treatment. In group B, 154 blood specimens were examined over 246 days' treatment.

Technique

Quick One-stage Prothrombin-time

Venous blood (5 ml.) was collected into a siliconed syringe (although siliconing of the syringe is not essential), and transferred to a bijou bottle containing a dried oxalate mixture (0·21 ml. of an aqueous solution containing 2·4% ammonium oxalate and 1·6% potassium oxalate dried at 37°C in an incubator for 36 hours). The blood and oxalates were thoroughly mixed. The blood was then centrifuged at 3500 r.p.m. in a 13×100 mm. test-tube for 5 minutes. The supernatant plasma was decanted into another tube. The thromboplastin reagent was prepared from acetone-dried human brain. A phenol-saline extract was prepared (Powell 1957) which gave normal prothrombin-times of 11–12 seconds. A dilution curve was obtained by the saline dilution of normal plasma, the results from six normal subjects were averaged. On this curve, readings of 19–30 seconds represented 30–15% prothrombin activity. The same batch of brain was used throughout the investigation. The calcium-chloride reagent used was 0·18% $CaCl_2$, and it was prepared from a stock 1% solution checked by chemical analysis. This reagent was warmed to 37°C before use.

The test proper consisted in pipetting 0·1 ml. thromboplastin reagent into a 10×70 mm. test-tube in a 37°C water bath, and allowing the reagent to warm up for at least five minutes. The reagent could be incubated up to 2 hours without deterioration. The test plasma (0·1 ml.) was then added, and the contents of the tube were mixed gently. Within 20 seconds of mixing, 0·1 ml. of the warm calcium chloride was added, a stopwatch being started simultaneously. The tube was tilted to and fro until a clot was seen to form. Three tests were made on each specimen, and the results averaged. All tests were performed within an hour of collecting the venous-blood specimen.

P & P Method of Owren and Aas (1951)

Venous blood (1·8 ml.) was collected into a siliconed syringe (although siliconing of the syringe is not essential), and transferred to a *siliconed* bijou bottle containing 0·2 ml. trisodium citrate (3·13%). The anticoagulant used in this test usually contains heparin to prevent activation of clotting factors by contact with glass. We preferred to use a siliconed container so that the same specimen of blood might also be used for the thrombotest, thus obviating the use of heparin which would interfere with the latter test.

The blood and citrate were thoroughly mixed, and the specimen was centrifuged in the same siliconed bijou bottle. Supernatant plasma (0·1 ml.) was removed immediately before the test, and the 1 in 10 dilution was prepared in the usual manner. The bovine plasma obtained from an abattoir was adsorbed twice with barium sulphate, as recommended by Biggs and Macfarlane (1957). The saline extract of human brain was obtained in the following way. Human brain was freed from meninges and blood-vessels, washed with distilled water, cut into small pieces, and transferred to a large mortar. Warm saline at 42°C was added in small quantities, and the tissue was pounded with a pestle In all 1500 ml of saline was added The thick supernatant suspension was distributed into 1 oz screw-capped universal containers, incubated at 37°C for 30 minutes, and then centrifuged to give a clear supernatant which was distributed into bijou bottles The bijou bottles were stored at −20°C This extract was found to give clotting times of 30–32 seconds with normal plasma A citrate-saline dilution curve was prepared in the usual way The same batch of thromboplastin reagent was used throughout the investigation

The same specimen of blood was used for both P & P test and thrombotest The thrombotest was always performed before the P & P test, removal of plasma for the P & P test could otherwise have interfered with the thrombotest by altering the red-cell volume

Thrombotest

Owren (1959) recommended that either venous or capillary blood could be used for this test We decided to use venous blood only, because with capillary blood there is always the danger of contamination of the specimen with a high concentration of tissue thromboplastin Non-wettable syringes and containers must be used for the collection of the venous-blood specimen, because contact with glass shortens the clotting times and gives misleading results for the assessment of anticoagulant dosage

Apparatus

Waterbath at 37°C, containing a metal test-tube rack with holes to accommodate 10×70 mm test-tubes

Pipette for measuring calcium chloride (11 ml) for reconstituting the lyophilised thrombotest reagent *

Pipette (0 5 ml) for thrombotest reagent *

Pipette (0 1 ml) for blood sample *

Syringes and bijou bottles siliconed with dimethyl dichlorosilane reagent in a fume cupboard The silicone reagent bottle was handled with protective rubber gloves The fumes are dangerous if inhaled The reagent was drawn into the syringes, left in contact for 1 minute, and returned to the stock bottle in the fume cupboard The bijou bottles were filled to the neck, and after 5 minutes the reagent was carefully decanted back into the stock bottle The barrels and plungers were separated and washed in slowly running tap water continuously for 10 days The bijou bottles were treated similarly A final rinse with distilled water was given, and the washings were found to be neutral with B D H universal indicator One coating with the silicone reagent seemed to provide a permanent non-wettable surface For convenience a 2 ml graduation mark was made on the exterior surface of the bijou bottles

Chemically clean 10×70 mm test-tubes

Reagents

Thrombotest reagent —The lyophilised reagent in an ampoule was reconstituted with the calcium-chloride solution (see below) by gently mixing and incubating the resulting suspension, at 37°C, in a water bath for 1 hour The reagent was gently mixed before use When not required the reagent ampoule was stoppered and stored at 4°C, it was found to be stable for 4 days if the precaution of storing at 4 C was carefully observed Four batches supplied by the manufacturers were used, and these gave different readings with normal venous blood Each batch was supplied with its own dilution curve Normal readings varied from 34 to 43 seconds with different batches of reagent

Calcium chloride (3 2 mM solution)

Venous blood was collected as for the P & P test with a siliconed syringe Thus the same specimen could be used for the two tests Venous blood (1 8 ml) was added to the 0 2 ml trisodium citrate (3 13%) anticoagulant in the graduated bijou bottle The contents were gently mixed In all other respects the technique was as described by Owren (1959)

Procedure

Thrombotest reagent (0 5 ml) was pipetted into a 10×70 mm test-tube and left to warm in the 37°C bath for at least 3 and not more than 30 minutes The venous-blood sample was gently mixed, and as 0 1 ml was pipetted into the tube containing the thrombotest reagent a stopwatch was started simultaneously The tube was gently tilted in the waterbath until a firm solid clot had formed The percentage activity was then read from the dilution curve supplied by the manufacturers of the reagent

Thromboplastin-generation Test

The procedure was as described by Biggs and Douglas (1953), except for the use of brain extract instead of platelet suspension (Bell and Alton 1954) The 6-minute reading was used for assessing the rate of thromboplastin generation The results were related to a dilution curve prepared each day from a normal subject The results of the T G T were plotted graphically for each patient during the course of treatment, and compared with the graphed results of the Quick, P & P, and thrombotest methods

The correlations between T G T and each of the three methods mentioned above were then broadly assessed as being good, moderate, or poor in the forty-three patients investigated

To check the constancy of the results of the T G T a control group, comprising six hospital patients with no clinical evidence of thrombosis, was studied daily for 10 days The test was found to give consistent results with the same batch of platelet substitute

Results

Detailed results are shown in table I

Group A

The patients in this group were controlled by the Quick test and were kept within the accepted therapeutic range (15–30% prothrombin activity) for over 80% of the period of treatment

All patients were tested before treatment and then daily until the therapeutic range was reached All results were included in the analysis, but had the initial results been excluded the proportion of tests within the therapeutic range would have been even higher

The P & P test and thrombotest correlated well throughout, but the results were not directly comparable with those of the Quick test Patients were within the P & P therapeutic range (10–30% activity) for only about half the period of treatment For the thrombotest, it has been suggested by Owren that the therapeutic range is also 10–30% activity Patients were only maintained within this thrombotest range for about two-thirds of the period of treatment

Many results were below the lower limit of the thrombotest and P & P therapeutic range—i e, less than 10% activity On the other hand, with the Quick test very few were below its lower limit—i e, *less than 15% prothrombin activity*

Group B

The patients in this group were controlled by thrombotest, and these results were compared with the results of the Quick test

TABLE I—COMPARISON OF THE RESULTS (IN TEST DAYS) OF QUICK, P & P, AND THROMBOTEST METHODS

Group	No of patients	Total no of test days	Total days treatment	Quick (range 15 to 30%)		P & P (range 10 to 30%)		Thrombotest (range 10 to 30 %)	
				Results above range	Results below range	Results above range	Results below range	Results above range	Results below range
A	31	415	530	76 (*18 3%*)	6 (*1 5%*)	16 (*3 9%*)	178 (*42 9%*)	12 (*2 9%*)	127 (*30 6 %*)
				within range *80 2* %		within range *53 2%*		within range *66 5*	
B	12	154	246	45 (*29 2%*)	1 (*0 7%*)			8 (*5 2%*)	29 (*18 8%*)
				within range *70 1%*				within range *76 0* %	

---

* Pipettes specifically designed for the test can be obtained commercially if necessary

Over three-quarters of the patients were kept within the recommended 10–30% range The results with the Quick test were found to be different from those in group A. Thus the number above the upper therapeutic range—i e , over the 30% upper limit of the Quick test—was considerably higher

Results of Thromboplastin-generation Test

The correlation between the Quick test and T G T in group A was

Test	*Good*	*Moderate*	*Poor*
Quick	7	12	12
P & P	14	6	11
Thrombotest	13	8	10

and the correlation in group B was

Test	*Good*	*Moderate*	*Poor*
Quick	4	–	4
Thrombotest	6	2	4

Good correlation between the two tests was found in less than a quarter of the patients The P & P test and thrombotest, on the other hand, correlated well about twice as often. But the correlation was only moderate or poor in more than half the patients In figs 1 and 2 examples are given of good and poor correlation between the T G T and other tests

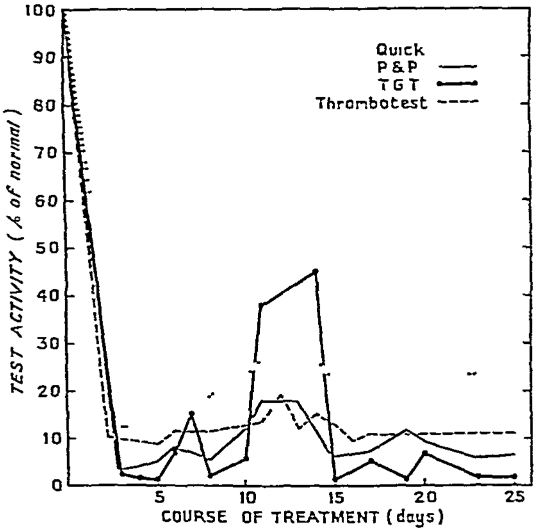

Fig 1—Good correlation between T G T and the three tests

Good correlation was usually found when there was much depression of the coagulation factors Thus, when the T G T , thrombotest, and P & P test correlated well, the Quick results were usually in the therapeutic range of 15–30% In contrast, where the Quick test showed results above 30% activity, correlation between the T G T and the other tests was relatively poor

In nineteen of the forty-three patients a fluctuating pattern of thromboplastin generation was observed during the course of phenindione treatment There was no obvious correlation between the T G T fluctuation and the Quick prothrombin activity or the dosage of anticoagulant

In a further six cases evidence of these fluctuations was doubtful The remaining sixteen cases showed no evidence of " spontaneous " fluctuation in the pattern of thromboplastin generation.

A fluctuating pattern of thromboplastin generation was considered to be present if a trend was observed in consecutive tests during treatment. The results were classed as doubtful where such a fluctuation was observed only in isolated tests Fig 3 shows a typical fluctuating thromboplastin-generation pattern, together with the results of the Quick, P & P, and thrombotest

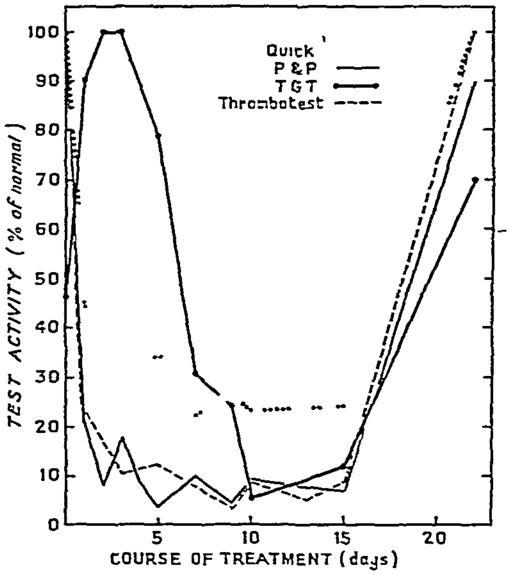

Fig 2—Poor correlation between T G T and the three tests

In contrast the six controls (hospital patients without clinical evidence of thrombosis) gave a consistent 100% thromboplastin generation in all estimations made over a 10-day period.

The forty-one treated patients were classified into 4 groups—i e., thrombotic (proved cases), doubtful thrombotic, non-thrombotic, and cases of angina pectoris The presence of fluctuating thromboplastin generation patterns in these groups is seen in table II, about 50% of the proved thrombotic cases showing these fluctuations

In eleven patients *before treatment*, the results of the T G T showed that thromboplastin generation was increased—i e , was above 100%—when compared with normal controls Six were patients with proved thrombosis, and four had suspected but not proved thrombosis One had angina pectoris In all these cases the Quick test, the P & P test, and thrombotest did not reflect this increase in thromboplastin activity In fact, in five cases thrombo-

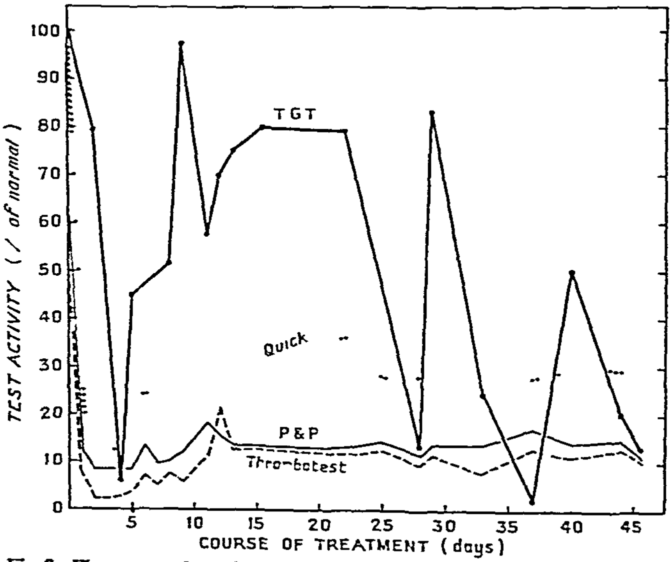

Fig 3—Fluctuating thromboplastin-generation pattern during phenindione treatment.

tissue was pounded with a pestle. In all 1500 ml. of saline was added. The thick supernatant suspension was distributed into 1 oz. screw-capped universal containers, incubated at 37°C for 30 minutes, and then centrifuged to give a clear supernatant which was distributed into bijou bottles. The bijou bottles were stored at −20°C. This extract was found to give clotting times of 30–32 seconds with normal plasma. A citrate-saline dilution curve was prepared in the usual way. The same batch of thromboplastin reagent was used throughout the investigation.

The same specimen of blood was used for both P. & P. test and thrombotest. The thrombotest was always performed before the P. & P. test, removal of plasma for the P. & P. test could otherwise have interfered with the thrombotest by altering the red-cell volume.

Thrombotest

Owren (1959) recommended that either venous or capillary blood could be used for this test. We decided to use venous blood only, because with capillary blood there is always the danger of contamination of the specimen with a high concentration of tissue thromboplastin. Non-wettable syringes and containers must be used for the collection of the venous-blood specimen, because contact with glass shortens the clotting times and gives misleading results for the assessment of anticoagulant dosage.

Apparatus

Waterbath at 37°C, containing a metal test-tube rack with holes to accommodate 10 × 70 mm. test-tubes.

Pipette for measuring calcium chloride (11 ml.) for reconstituting the lyophilised thrombotest reagent.*

Pipette (0.5 ml.) for thrombotest reagent.*

Pipette (0.1 ml.) for blood sample.*

Syringes and bijou bottles siliconed with dimethyl dichlorosilane reagent in a fume cupboard. The silicone reagent bottle was handled with protective rubber gloves. The fumes are dangerous if inhaled. The reagent was drawn into the syringes, left in contact for 1 minute, and returned to the stock bottle in the fume cupboard. The bijou bottles were filled to the neck, and after 5 minutes the reagent was carefully decanted back into the stock bottle. The barrels and plungers were separated and washed in slowly running tap water continuously for 10 days. The bijou bottles were treated similarly. A final rinse with distilled water was given, and the washings were found to be neutral with B.D.H. universal indicator. One coating with the silicone reagent seemed to provide a permanent non-wettable surface. For convenience a 2 ml. graduation mark was made on the exterior surface of the bijou bottles.

Chemically clean 10 × 70 mm. test-tubes.

Reagents

Thrombotest reagent.—The lyophilised reagent in an ampoule was reconstituted with the calcium-chloride solution (see below) by gently mixing and incubating the resulting suspension, at 37°C, in a water bath for 1 hour. The reagent was gently mixed before use. When not required the reagent ampoule was stoppered and stored at 4°C, it was found to be stable for 4 days if the precaution of storing at 4°C was carefully observed. Four batches supplied by the manufacturers were used, and these gave different readings with normal venous blood. Each batch was supplied with its own dilution curve. Normal readings varied from 34 to 43 seconds with different batches of reagent.

Calcium chloride (3.2 mM solution).

Venous blood was collected as for the P. & P. test with a siliconed syringe. Thus the same specimen could be used for the two tests. Venous blood (1.8 ml.) was added to the 0.2 ml. trisodium citrate (3.13%) anticoagulant in the graduated bijou bottle. The contents were gently mixed. In all other respects the technique was as described by Owren (1959).

Procedure

Thrombotest reagent (0.5 ml.) was pipetted into a 10 × 70 mm. test-tube and left to warm in the 37°C bath for at least 3 and not more than 30 minutes. The venous-blood sample was gently mixed, and as 0.1 ml. was pipetted into the tube containing the thrombotest reagent a stopwatch was started simultaneously. The tube was gently tilted in the waterbath until a firm solid clot had formed. The percentage activity was then read from the dilution curve supplied by the manufacturers of the reagent.

Thromboplastin-generation Test

The procedure was as described by Biggs and Douglas (1953), except for the use of brain extract instead of platelet suspension (Bell and Alton 1954). The 6-minute reading was used for assessing the rate of thromboplastin generation. The results were related to a dilution curve prepared each day from a normal subject. The results of the T.G.T. were plotted graphically for each patient during the course of treatment, and compared with the graphed results of the Quick, P. & P., and thrombotest methods.

The correlations between T.G.T. and each of the three methods mentioned above were then broadly assessed as being good, moderate, or poor in the forty-three patients investigated.

To check the constancy of the results of the T.G.T. a control group, comprising six hospital patients with no clinical evidence of thrombosis, was studied daily for 10 days. The test was found to give consistent results with the same batch of platelet substitute.

Results

Detailed results are shown in table I.

Group A

The patients in this group were controlled by the Quick test and were kept within the accepted therapeutic range (15–30% prothrombin activity) for over 80% of the period of treatment.

All patients were tested before treatment and then daily until the therapeutic range was reached. All results were included in the analysis, but had the initial results been excluded the proportion of tests within the therapeutic range would have been even higher.

The P. & P. test and thrombotest correlated well throughout, but the results were not directly comparable with those of the Quick test. Patients were within the P. & P. therapeutic range (10–30% activity) for only about half the period of treatment. For the thrombotest, it has been suggested by Owren that the therapeutic range is also 10–30% activity. Patients were only maintained within this thrombotest range for about two-thirds of the period of treatment.

Many results were below the lower limit of the thrombotest and P. & P. therapeutic range—i.e., less than 10% activity. On the other hand, with the Quick test very few were below its lower limit—i.e., less than 15% prothrombin activity.

Group B

The patients in this group were controlled by thrombotest, and these results were compared with the results of the Quick test.

TABLE I—COMPARISON OF THE RESULTS (IN TEST DAYS) OF QUICK, P. & P., AND THROMBOTEST METHODS

Group	No. of patients	Total no. of test days	Total days treatment	Quick (range 15 to 30%)		P. & P. (range 10 to 30%)		Thrombotest (range 10 to 30%)	
				Results above range	Results below range	Results above range	Results below range	Results above range	Results below range
A	31	415	530	76 (*18.3%*)	6 (*1.5%*)	16 (*3.9%*)	178 (*42.9%*)	12 (*2.9%*)	127 (*30.6%*)
				within range *80.2%*		within range *53.2%*		within range *66.5%*

Over three-quarters of the patients were kept within the recommended 10–30% range The results with the Quick test were found to be different from those in group A. Thus the number above the upper therapeutic range—i e., over the 30% upper limit of the Quick test—was considerably higher

Results of Thromboplastin-generation Test

The correlation between the Quick test and T G T in group A was

Test	*Good*	*Moderate*	*Poor*
Quick	7	12	12
P & P	14	6	11
Thrombotest	13	8	10

and the correlation in group B was

Test	*Good*	*Moderate*	*Poor*
Quick	4	4	4
Thrombotest	6	2	4

Good correlation between the two tests was found in less than a quarter of the patients The P & P test and thrombotest, on the other hand, correlated well about twice as often. But the correlation was only moderate or poor in more than half the patients In figs 1 and 2 examples are given of good and poor correlation between the T G T and other tests

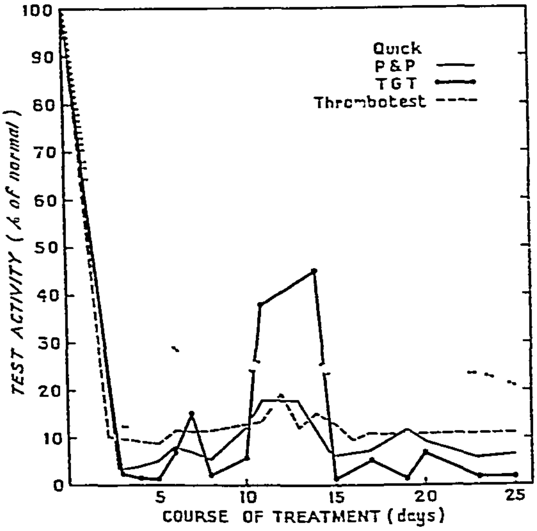

Fig 1—Good correlation between T G T and the three tests

Good correlation was usually found when there was much depression of the coagulation factors Thus, when the T G T, thrombotest, and P & P test correlated well, the Quick results were usually in the therapeutic range of 15–30% In contrast, where the Quick test showed results above 30% activity, correlation between the T G T and the other tests was relatively poor

In nineteen of the forty-three patients a fluctuating pattern of thromboplastin generation was observed during the course of phenindione treatment There was no obvious correlation between the T G T fluctuation and the Quick prothrombin activity or the dosage of anticoagulant

In a further six cases evidence of these fluctuations was doubtful The remaining sixteen cases showed no evidence of "spontaneous" fluctuation in the pattern of thromboplastin generation

A fluctuating pattern of thromboplastin generation was considered to be present if a trend was observed in consecutive tests during treatment The results were classed as doubtful where such a fluctuation was observed only in isolated tests Fig 3 shows a typical fluctuating thromboplastin-generation pattern, together with the results of the Quick, P & P, and thrombotest

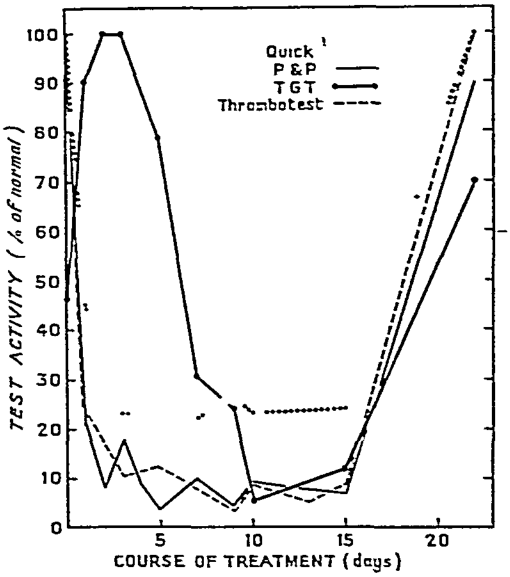

Fig 2—Poor correlation between T G T and the three tests.

In contrast the six controls (hospital patients without clinical evidence of thrombosis) gave a consistent 100% thromboplastin generation in all estimations made over a 10-day period

The forty-one treated patients were classified into 4 groups—i e., thrombotic (proved cases), doubtful thrombotic, non-thrombotic, and cases of angina pectoris The presence of fluctuating thromboplastin generation patterns in these groups is seen in table II, about 50% of the proved thrombotic cases showing these fluctuations

In eleven patients *before treatment*, the results of the T G T showed that thromboplastin generation was increased—i e, was above 100%—when compared with normal controls Six were patients with proved thrombosis, and four had suspected but not proved thrombosis One had angina pectoris In all these cases the Quick test, the P & P test, and thrombotest did not reflect this increase in thromboplastin activity In fact, in five cases thrombo-

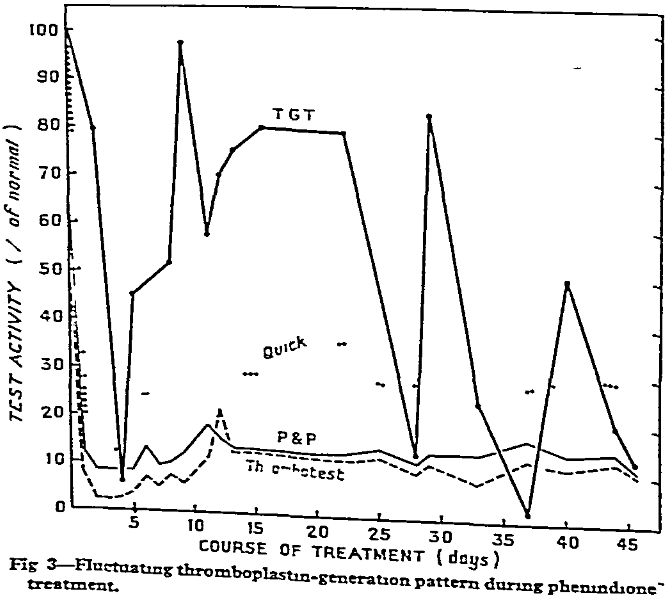

Fig 3—Fluctuating thromboplastin-generation pattern during phenindione treatment.

TABLE II—T G T PATTERNS IN PATIENTS TREATED WITH ANTICOAGULANTS

T G T pattern	Cases			
	Thrombotic	Doubtful thrombotic	Non-thrombotic	Angina
Fluctuating	13	2	0	5
Doubtful	3	1	1	0
Non fluctuating	11	7	0	0

test gave results below 100%, suggesting that thromboplastin generation was decreased

In six patients thromboplastin generation was depressed before anticoagulant treatment had been instituted Four of these showed depressed Quick prothrombin activity and a prolonged thrombotest, whereas only three gave a prolonged P & P test

In twenty-one patients the thromboplastin-generation test returned to normal or near normal during the course of phenindione treatment, although the Quick test was within the therapeutic range

The speed with which thromboplastin generation was depressed to 30% or less during phenindione treatment varied considerably In fig 4 the day on which such depression was first observed has been plotted for the whole series

Thrombotest and the Prediction of Hæmorrhage

Three non-fatal hæmorrhagic episodes arose during the course of treatment of the forty-three patients—two in group A and one in group B These incidents represent one non-fatal hæmorrhage per 8 months of short-term treatment On each occasion the Quick prothrombin activity was still within the therapeutic range, whereas the thrombotest was below 10%, and the thromboplastin generation less than 5% In the two patients of group A the P & P test was also less than 10% of normal

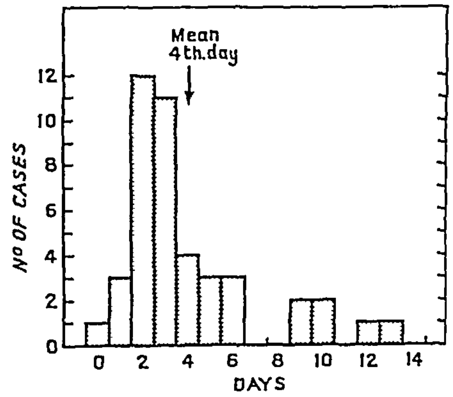

Fig 4—Days before thromboplastin generation was first observed below 30% of normal in forty-three patients on phenindione treatment

Death during Anticoagulant Treatment

There were four deaths—two in each group The numbers are too small for any conclusion to be drawn

Thromboembolic Complications

No thromboembolic episode was observed clinically in either group

Discussion

The Quick test, first described in 1935, has been the sheet anchor for the control of oral anticoagulants since their introduction nearly 20 years ago There have been many modifications of the test, but the basic principles have remained unchanged The main difficulty encountered has been the standardisation of the thromboplastin extracts Acetone-dried human brain, which has been prepared easily in our laboratory, has been found to give reproducible results Most modifications of the Quick test are sensitive to depressions of factor VII and prothrombin, which occur during treatment with oral anticoagulants The use of a powerful tissue-thromboplastin reagent in Quick's test makes it impossible to measure changes in factors involved in the production of intrinsic blood thromboplastin Several workers have shown that depression of thromboplastin generation also occurs during anticoagulant treatment (Biggs et al 1953, Hunter and Walker 1954, Koller 1954, 1955) Christmas factor and Prower-Stuart factor are involved in thromboplastin production, and both of these are reduced by the anticoagulants (Douglas 1955, Hougie et al 1957) Changes in Christmas factor are not measured by Quick's test

Our results relate to the Quick test performed with one particular type of thromboplastin reagent—i e, acetone-dried human brain—the same batch being used throughout the investigation Results with this batch were similar to those with previous batches we have prepared regularly over the past 13 years Commercial preparations are known to give variable results owing to variable degrees of factor-VII contamination (Verstraete et al 1957)

Hicks and Bonnin (1959) have suggested that, in the majority of patients, depression of thromboplastin generation by anticoagulants runs parallel with the depression of Quick's test, but they gave instances in which this relationship was not close In contrast, our results indicate that only in a minority is there good correlation between the two tests The Quick prothrombin time thus appears to be an incomplete measure of the anticoagulant effect produced by anticoagulants

Results with the P & P test and thrombotest were slightly better, but correlation was good in less than half the cases

Waaler (1957) showed that the P & P test was slightly sensitive to reduction in Christmas factor when low levels of factor VII and prothrombin had been attained From our investigations we gained the impression that the P & P test and thrombotest correlate well only when these extrinsic factors are considerably depressed

In the three cases having phenindione treatment, where there was spontaneous bleeding, the thrombotest indicated a dangerous depression of coagulability This is important since all three had seriously impaired thromboplastin generation, although the Quick prothrombin times were within the "therapeutic range"

In about *half* the patients a fluctuating pattern of thromboplastin generation could not obviously be related to the dosage of anticoagulant drug Such fluctuations do not seem to have been reported previously Their pattern is remarkably similar to the fluctuating coagulability pattern observed with heparin-plasma-clotting tests in patients with recent thrombosis who are not having anticoagulant drugs (Poller 1954, 1956)

Several workers have reported increased *thromboplastin* generation in patients with recent thrombosis (Poller 1957, MacDonald 1959, Spittel et al 1960) Thrombotest appears insensitive to such changes in contrast to heparin-clotting-time methods, which *may* register a thrombotic tendency The observation that the T G T was appreciably impaired in six cases before anticoagulant therapy was commenced is of interest In most of these cases there appeared to be a combined *defect* of coagulation factors, including prothrombin and associated factors

The day on which appreciable depression of thromboplastin generation was first registered was by *no means* constant, varying from the start of treatment to 13 days later This point has not been emphasised by previous workers, although impairment of intrinsic blood-thromboplastin generation, when the Quick prothrombin time was normal or only slightly prolonged, was observed by Koller (1954) and by Hunter and Walker (1954)

Our results suggest that the therapeutic ranges of the Quick test, the P & P method, and thrombotest are not directly comparable Either the accepted lower limit of 15% in the Quick test (using acetone-dried human brain as thromboplastin reagent) denotes too great a depression of clotting factors, or the lower limit of 10% with P & P or thrombotest is too high

Bjerkelund (1957) and other Scandinavian workers have employed the 10% lower limit, using the P & P method, for several years, with good results—i e , low incidence of complications From comparison of the Quick test and the P & P method, Smith and Schelling (1955) are of the opinion that the therapeutic range with the Quick test should be 34–48% prothrombin activity

Our results suggest that excessive reduction of thromboplastin factors may be an important factor predisposing to hæmorrhage In our series there were four cases of hæmorrhage, in three of these the results with P & P and thrombotest were *below* the therapeutic level of 10%, and the T G T showed thromboplastin generation to be below 5% of normal In contrast the Quick test showed the prothrombin activity to be in the therapeutic range—i e , above 15%—thus failing to give sufficient warning of possible hæmorrhage

It is as yet too early to define exactly the therapeutic limits with the thrombotest technique The similarity between P & P and thrombotest results suggest that the range will be 10–30%

The chief advantage of thrombotest is that it makes available to all laboratories a simple test which gives results as reliable as the more complicated P & P test On the other hand, there are disadvantages when it is compared with the Quick prothrombin-time test Amongst these are the greater care necessary in collecting blood specimens, and in preparing the glassware and syringes Although the siliconing of glassware appears simple, it is not without risks in unskilled hands Reconstitution of the freeze-dried thrombotest reagent requires great care One of the batches tested contained an agglutinin which gave agglutination similar to that obtained with human blood-group antibody, and this interfered with the reading of the end-point in some cases

Since more and more patients are being treated with anticoagulants, a great disadvantage is the high cost of imported thrombotest reagent Owren (1960) has shown that half quantities of the reagent give as reliable results and afford economy The general principles for preparing the reagent have been described (Owren 1959), but whether such an elegant and reliable lyophilised preparation would be obtained in a hospital laboratory remains to be seen The cost of a home-made preparation must also be appreciable If thrombotest does give some warning of possible hæmorrhages when in fact the Quick test does not, then there is a good case for introducing the newer test at the earliest opportunity In the meantime it seems advisable to keep the Quick prothrombin time between $1^{1}/_{2}$ and 2 times normal—i e , 30–20% prothrombin activity—where this established test is still being used For many years this plan has been adopted by one of us (H L), and it has proved satisfactory from the point of view of hæmorrhagic complications Toohey (1958) pointed out that the P & P method was superior to the Quick method for assessing dosage at the start of anticoagulant therapy, on the other hand, for outpatient long-term therapy, where specimens were taken at fairly long intervals, the Quick method was still reliable From our results with thrombotest similar conclusions may be drawn

Summary

Two groups of patients having anticoagulant therapy were studied

In group A, comprising thirty-one patients, anticoagulant dosage was based on Quick's prothrombin-time test, and simultaneous observations were made by Owren's thrombotest method, the prothrombin and proconvertin (P & P) method, and a thromboplastin-generation test

In group B, comprising twelve patients, anticoagulant dosage was based on Owren's thrombotest method, and simultaneous observations made by Quick's test and a thromboplastin-generation test

When group A patients were controlled by Quick's method about 30% of the simultaneous thrombotest results were below the therapeutic range, suggesting that too much anticoagulant was given

When group B patients were controlled by the thrombotest method about 30% of the simultaneous Quick test results were above the therapeutic range, suggesting that not enough anticoagulant was given

Among the forty-three patients there were three non-fatal hæmorrhages, and in each of these the Quick test results were within the therapeutic range whereas the thrombotest results were below the therapeutic range

Fluctuation of intrinsic thromboplastin factors was studied during treatment

Before the Quick test is replaced by the thrombotest in routine control of anticoagulant treatment more experience is required Meanwhile it is suggested that safer control will be obtained if the Quick prothrombin time, using the described acetone-dried brain extract, is kept at not more than twice normal, and the thrombotest at not more than 3 to $3^{1}/_{2}$ times normal No one-stage method is entirely safe in controlling anticoagulant treatment

We wish to express our thanks to the following members of the Department of Clinical Pathology, Manchester Royal Infirmary, who so ably assisted us in this investigation Miss Jean Carr, F I M L T , hæmatological technician, Dr M J Lewis, registrar in pathology, and Dr A L Buckley, resident clinical pathologist We also wish to thank Prof P A Owren for sending us preliminary information about thrombotest, and Messrs Nygaard & Co , of Oslo, for a generous supply of the reagent We are grateful to Evans Medical, Ltd , for augmenting our supplies of the reagent, and to Dr M C G Israels for his helpful criticism in the preparation of this paper

CARDIAC ARREST
TREATED BY ELEVATION OF THE LIMBS FOR FIFTEEN SECONDS

W W WOODWARD
M B Sydney, F R C S, F R A C S

HONORARY SURGEON TO INPATIENTS, GENERAL HOSPITAL,
LAUNCESTON, TASMANIA

FILLING the arrested heart with blood from the patient's elevated limbs can restart beating, as I have already reported (Woodward 1952) The same observation was made by Fowler (1952), and the method has been used experimentally (Stephenson 1958) Blood can be transferred to the heart by gravity by raising the limbs vertically In states of reduced blood-volume, bandaging the limbs can help further, but experience has convinced me that, apart from this one indication, bandaging is unnecessary

On four occasions, I have confirmed the effectiveness of this method when the chest has been open [Launceston General Hospital numbers 77082, 81204, U R 7913, U R 14234], thoracotomy allowing direct observation of the heart while the limbs were raised In these four patients, mere elevation of the unbandaged limbs rapidly restored cardiac contractions Having seen these responses, I concluded that, provided two conditions are fulfilled, raising the limbs vertically before incising the *precordium* could be of value The provisos are (1) cardiac arrest has been immediately recognised, and (2) no more than fifteen seconds are spent in the manœuvre This method has been carried out on three occasions, and there has been no need for thoracotomy

Case-records

Case 1 —A B, aged 62, [U R 1781], on March 13, 1956, was given thiopentone and gallamine triethiodide intravenously for bronchoscopy During the operation, cardiac pulsation, seen through a bronchoscope in the left main bronchus, ceased The anæsthetist could not detect the radial or carotid pulses, and gave intratracheal oxygen under positive pressure, but without effect The patient's legs were *immediately* held vertically and, before the precordium could be incised, the heartbeat returned and the patient recovered consciousness

Case 2 —A C, aged 54, was admitted [U R 8358] on Dec 29, 1957, with severe hæmatemesis and melæna After eleven bottles of stored blood, he was still in coma but a direct transfusion was followed by sufficient improvement to allow operation When the stomach was opened, its wall did not bleed The aorta was palpated immediately there was no pulsation The patient's four limbs were immediately held vertically and, within fifteen seconds, the pulse returned After completion of partial gastrectomy, he recovered consciousness

Case 3 —A D, aged 61 was to undergo a left axillary dissection in St Vincent's Hospital, Launceston, on Sept 26, 1958 General anæsthesia was induced with thiopentone and gallamine triethiodide by Dr K S Goulston who soon after induction noticed absence of radial and carotid pulses, could hear no heart-sounds, nor measure the blood-pressure All visible parts of the skin became deathly pale and both pupils were widely dilated The theatre sister immediately held the legs vertical while her assistant did the same to the arms Oxygen was given, but it is well known (Stephenson 1958) that, though necessary, this is not effective alone Within fifteen seconds the pulse returned Operation was postponed, and the patient recovered consciousness Four days later the axillary dissection was performed without trouble

Summary

In rapidly recognised cardiac arrest, the pulse has been restored within fifteen seconds of raising the limbs into the upright position—on one occasion, the legs only, and at other times, all four limbs

Though cardiac massage is still the main method of treatment, it can at times be forestalled

THE committee on toxicology of the American Medical Association (1959) advised the use of intravenous infusions of edathamil calcium-disodium (calcium disodium versenate) in the treatment of acute iron poisoning Since few reports have been published on the efficacy of this agent in acute iron poisoning we present the results obtained in a severe case

Case-record

A boy, aged 2, weighing 31½ lb (14 3 kg), was admitted two hours after swallowing about forty 5-grain (total amount 320 mg) tablets of ferrous sulphate He vomited an unknown number half an hour after taking them, and his stomach was later washed out at another hospital

On admission (10 40 A M, Feb 15, 1960), he was in severe shock and was unconscious The blood-pressure was too low to record Tetracycline was given intramuscularly, and an intravenous infusion of plasma was started at 11 A M Three-quarters of an hour later the radial pulse became palpable Edathamil 0 5 g in 400 ml plasma was given intravenously from 12 15 P M to 3 P M During the afternoon he passed several black fluid stools and vomited small amounts of blood The plasma-bicarbonate at 3 45 P M was 12 mEq per litre, and 80 ml *M* sodium lactate was given intravenously during the ensuing forty-eight hours From 7 P M on Feb 15 to 10 A M on Feb 16, 0 5 g of edathamil was given intravenously in 600 ml of 5% dextrose Consciousness gradually returned during Feb 16, and on the following day he began to take milk drinks The intravenous infusion was continued with 5% dextrose solution, and a third dose of 0 5 g of edathamil was given on Feb 17

During the night of Feb 17–18 he became increasingly restless, and by noon on Feb 18 was semiconscious, with acetonic breath and twitching limbs The liver on palpation was small and abnormally firm Blood-pressure, blood-glucose, and plasma-non-protein nitrogen levels were normal A diagnosis of hepatic coma was made, milk drinks were stopped, and tetracycline was given by mouth Plasma was substituted for 5% dextrose infusion The first of several electroencephalograms (E E G) was taken By Feb 19 clinical jaundice was evident, and, during the morning, four convulsions occurred Towards evening he became easier to arouse, by the next day he was fully conscious and beginning to play with toys From this point his recovery was rapid and sustained Clinical jaundice had disappeared, and the liver appeared normal in size by Feb 23

At follow-up on April 11 the child appeared to be in good mental and physical health and no abnormality was found on clinical examination Electrophoresis of plasma proteins, plasma thymol-turbidity, and thymol-flocculation tests were normal

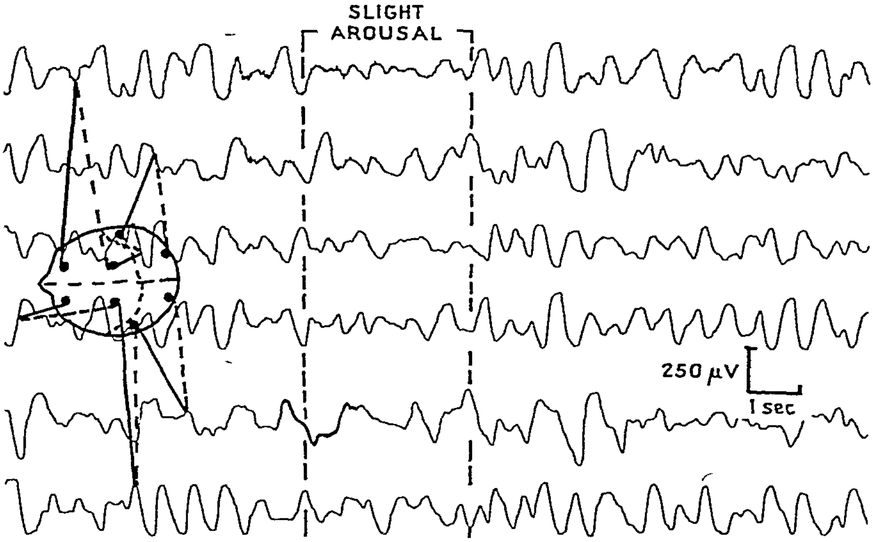

Fig 1—Electroencephalogram from a case of acute iron poisoning three days after admission.

Investigations

Serum-iron (µg per 100 ml by the method of Ramsay 1957)

Feb 15 12 15 P M	6260	Feb 16	4 30 P M	375
3 45 P M	1660	Feb 17	12 noon	314
6 45 P M	1000	Feb 18	9 30 A M	191
Feb 16 9 30 A.M	350	Feb 22	12 noon	105

Urinary iron —Urine was digested with nitric and perchloric acids as described by Collins and Diehl (1959) The iron content was then estimated by Ramsay's (1957) method

No urine was passed until 7 15 P M on Feb 15 From then until 5 P M on Feb 17, 761 ml urine, containing 5416 µg iron, was passed 3223 µg of this total was recovered between 7 15 P M and 11 15 P M on Feb 15

Serum transaminase (method of Reitman and Frankell [1957])

	Feb 15	*Feb 16*	*Feb 17*	*Feb 18*	*Feb 19*	*April 14*
Serum glutamic-oxaloacetic-transaminase	48	990	3400	2050	840	
serum glutamic-pyruvic-transaminase	25	700	2500	2400	1320	28

Other biochemical investigations —Total serum-bilirubin Feb 15, 0 25 mg per 100 ml , Feb 19, 4 1 mg Plasma-proteins Feb 15, 7 6 g per 100 ml , Feb 20, 4 9 g

Electroencephalography —Six E E G s were recorded The first, taken on Feb 18, was grossly pathological, showing large slow delta rhythms (1–2 cycles per second), up to 250 µV in amplitude, in all regions (fig 1) The patient was then comatose, but on one occasion, when he appeared to awaken spontaneously, the delta rhythms diminished considerably in amplitude for a few seconds The second record, taken a week later, when the patient was fully conscious though restless and irritable, showed a dramatic change The large delta rhythms had disappeared and there was very little rhythmic activity of any kind except for occasional runs of theta waves at 6–7 cycles per second (fig 2) Subsequent E E G showed a progressive return to normal, the last record, taken on March 3, being typical of the patient s age-group

Dr W Grey Walter thought the initial gross abnormality could have been due to direct specific neuronic intoxication, to a secondary disturbance of subcortical mechanisms as a result of hepatic dysfunction, or possibly to both

Discussion

In cases of acute iron poisoning by ingestion it is usually impossible to determine the amount absorbed because iron lost in vomit, gastric lavage, and bowel evacuations cannot be measured Serum-iron levels are usually regarded as indexes of iron transport, but they only indicate iron-content of the body within broad limits Experimentally, ferric iron dialyses slowly from serum even though iron-binding protein has been saturated (Laurell 1947) In ferrous sulphate poisoning, iron leaves the blood-stream rapidly, although probably present in ferric form (Reissmann et al 1955) Serum-iron levels in one of Spencer's cases (1951) fell from 3300 µg per 100 ml to 1120 µg in eleven hours In the case reported by Brown and Gray (1955), values fell from 5450 µg to 430 µg in thirty-nine hours

An estimate of total serum-iron based on the first determination made nearly four hours after the child took iron would be no more than a minimal approximation of the amount absorbed Assuming that his plasma-volume at the time was 5% of body-weight, the plasma-iron content was 44,100 µg In the fifty-three-hour period following the first serum-iron sampling, 5416 µg of iron, or 12% of the initial plasma-iron content, was recovered from the urine Of the iron excreted, three-fifths was found in the first urine passed after the initial edathamil infusion, but the second and third infusions were not followed by any rise in urinary iron excretion

Sunderman and Boerner (1949) quoted amounts ranging from 45 to 200 µg per twenty-four hours for normal urinary iron excretion The amount found in the urine of our patient represented a twelvefold increase of the maximum normal figure Increases in urinary iron excretion of the same order were found in hæmochromatosis (Figueroa et al 1955, Wishinsky et al 1955), hæmosiderosis (Greenwalt and Ayers 1955), and experimental iron poisoning (Foreman et al 1952), treated with chelating agents

Edathamil had little effect on the urinary iron excretion in our

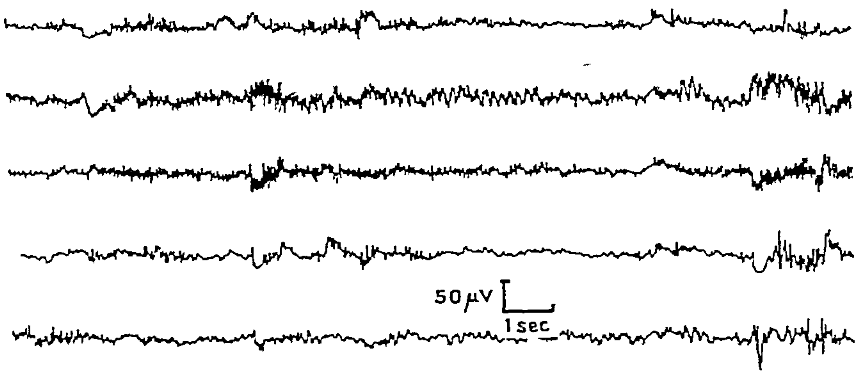

Fig 2—Electroencephalogram of same case seven days later

patient although serum-iron levels fell from 6260 µg per 100 ml to 1000 µg within seven hours If the drug increased diffusion of iron from the blood, it might be valuable in the first and most critical phase of iron intoxication in which shock with hæmoconcentration develops rapidly In rabbits poisoned with intravenous iron, shock developed within a few seconds (Brown and Gray 1955), it also appeared when animals were poisoned by intraduodenal instillation of iron in solution, a method which does not produce mucosal necrosis This evidence suggested that circulatory changes were a direct effect of excess iron in the vascular system If this were so, rapid removal of the excess might aid recovery from shock The rate of fall of serum-iron in our case did not appear to be faster than that recorded by Spencer (1951), whose case received no chelating agent Serum-iron levels in dogs poisoned with intraduodenal ferrous sulphate where higher in untreated animals than in those receiving edathamil intravenously immediately after iron was given (Bronson and Sisson 1960) Death was not prevented, however, and the amount of serum-iron did not appear to be the determining factor The only survivor was also given disodium orthophosphate into the stomach when iron was administered into the duodenum

The course of the child's illness followed closely the biphasic pattern emphasised by Prain (1949) and Spencer (1951) An initial period of shock, recovery from which could be attributed to the measures taken to increase plasma-volume and to correct acidosis, was followed about sixty hours later by a second period of coma The clinical diagnosis of hepatic coma was supported by very high levels of serum-transaminase, increased plasma-bilirubin values, changes in plasma-protein levels, and normal plasma-non-protein-nitrogen values The abnormal E E G records were also consistent with this diagnosis The second critical phase was successfully negotiated within forty-eight hours and recovery was then rapid The same sequence of events has been reported in severe cases which were not treated with chelating agents

Summary

A non-fatal case of acute iron poisoning in a boy, aged 2, is reported Treatment included the use of intravenous edathamil calcium-disodium (calcium disodium versenate), and its effect is discussed The plasma-iron content at the start of treatment was 44,000 µg In the following fifty-two hours 5416 µg of iron was found in the urine

The biphasic nature of the clinical course is again emphasised Relapse in our patient was the result of liver dysfunction

We are grateful to the consultant physicians of the department of child health and the department of pathology, United Bristol Hospitals, for their advice and their permission to publish this case

CANCER OF THE ŒSOPHAGUS

PALLIATION BY INTUBATION

W P GREENING
F R C S
ASSISTANT CONSULTANT SURGEON

G S RAMSAY
M B Lond, F R C S
RESEARCH ASSISTANT

THE ROYAL MARSDEN HOSPITAL, FULHAM ROAD, LONDON, S W 3

THE most important function of any palliative procedure in cases of inoperable cancer of the œsophagus or of the cardia is the relief of dysphagia Obstruction in the œsophagus or the upper end of the stomach cannot always be relieved by radiotherapy, Souttar's tubes have certain disadvantages, and gastrostomy is a most undesirable procedure

Recently there has been a revival of interest in methods of inserting a tube through the obstruction, either via an œsophagoscope (Weisel et al 1959, Sachs 1959) or through a gastrostomy opening (Gourevitch 1959, Moghissi 1960)

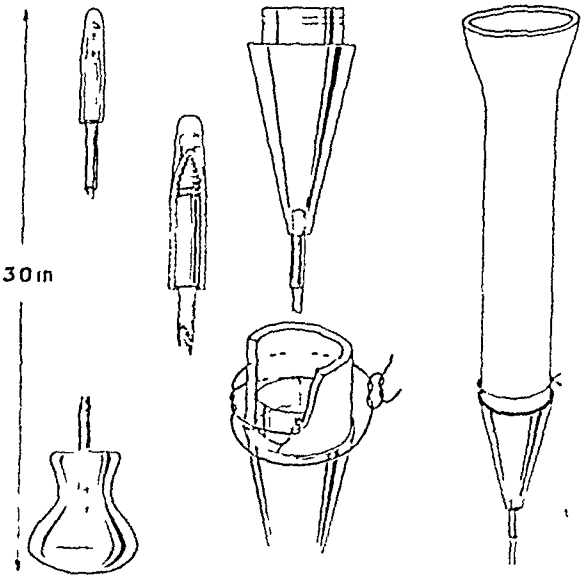
Ideally, after intubation, the patient should be able to swallow without difficulty, and there should be no restriction in the diet Gourevitch (1959) has summed up the main disadvantages of intubation through an œsophagoscope We would add another to his list—namely, the size of the tube that can be passed is limited by the diameter of the lumen of the œsophagoscope This is important because we believe that it is essential to insert as large a tube as possible, and this can only be done easily from below The danger of splitting the œsophagus, or of hæmorrhage from the growth, has been exaggerated, it is possible to dilate a malignant stricture much more widely than is generally believed

These points are important

1 The method should be simple Œsophagoscopy—particularly in the elderly patient—is not always either easy or safe

2 The tube should be of large diameter

3 The tube should be made of inert material, capable of being fashioned individually for each case, and available in different degrees of hardness to suit varying conditions



The œsophageal tube introducer

Over the past two years we have developed a method, used in 9 cases, which satisfies these requirements Polyvinyl chloride tubes, supplied in two degrees of hardness by Portland Plastics Limited, are used An introducer with interchangeable ends, to fit three different sizes of tube (numbers 30, 40, and 50), has been designed A flange is made at the upper end of the tube This can be done quite simply by immersing the end of the tube in boiling glycerin, at the temperature of which (290°C) it becomes easily malleable It is then passed over a conical object of suitable size, and, on cooling, the splayed-out end remains a permanent flange The introducer (see figure) consists of 30 in of Bowden cable with a screw-threaded end, to which can be attached either a small 'Perspex' tip, or one of three perspex cones The cable is coated with "cold-cure" 'Silastomer' (Midland Plastics Limited), this is a silicone rubber covering which is flexible and can be used at temperatures up to 200°C

Technique

The inoperability of the tumour is determined either clinically or at operation A high anterior gastrotomy is then made and the introducer, with the perspex tip attached, is passed up the œsophagus and delivered through the mouth by the anæsthetist The tip is then unscrewed and the appropriate cone attached These cones are so designed that the base fits into the lumen of the tube, while the rim of the cone, which is of slightly larger diameter than the outside diameter of the tube, does not project, and thus the tube cannot catch in the growth as it is pulled through The tube is tied to the base of the cone by a thread, passed through the wall of the tube and through the channel provided in the base of the cone Traction on the introducer then causes the tube to pass easily down the œsophagus, until the flange is just above the growth The cone is then detached, and any excess of tube cut off, so that the lower end lies in the upper third of the stomach The gastrotomy is closed

We wish to thank the department of medical physics at the Royal Marsden Hospital for making the instrument, and Midland Silicones Limited for the supply of "cold-cure" 'Silastomer'

Preliminary Communication

BLOOD-CHOLESTEROL AND ASPIRIN

ARTERIOSCLEROSIS and cardiac infarction are particularly important problems at the present time Many workers consider that there is a definite relationship between the blood-cholesterol level and arteriosclerosis Various diets have been tried in arteriosclerotic diseases, and attempts made to lower the blood-cholesterol level by administering linoleic acid Dreyfuss [1] observed a rise in the blood-uric-acid level in some cases of arteriosclerosis, but emphasised that the blood-cholesterol level was not invariably raised I have noted that in some cases of arteriosclerosis not only the blood-cholesterol but also the blood-uric-acid level is raised

On the assumption that there might be a metabolic relationship betweeen cholesterolæmia and raised blood-uric-acid levels, an attempt was made to lower the blood-cholesterol level by decreasing the blood-uric-acid For this purpose small quantities of aspirin (1 5 g daily) were administered to 10 patients (6 men and 4 women) whose ages ranged from 38 to 65 years 6 of them had had myocardial infarction and 1 of these was also hypertensive, 2 were hypertensive, 1 had recurrent anginal pain, and 1 had peripheral arteriosclerosis

BLOOD-CHOLESTEROL AND BLOOD-URIC-ACID (MG PER 100 ML) BEFORE, DURING, AND AFTER TREATMENT WITH ASPIRIN 1 5 G DAILY

Case no	Before treatment		After 2 weeks treatment		After 1 month s treatment		After end of treatment	
	Chol-esterol	Uric acid	Chol-esterol	Uric acid	Chol-esterol	Uric acid	Chol-esterol	Uric acid
1	270	4 7	240	4 7	180	4 0		
2	370	6 2	220	6 2			370	
3	310	4 2	175	3 2	228	3 2		
4	330	5 2	286	5 0	230	6 0	310	6 2
5	270	4 0	230	5 0			300	4 2
6	350	4 8	280	4 0				
7	331	4 3	190	3 7				
8	240	5 0	198	4 35	215	5 4		
9	300	4 0	135	3 25				
10	342	4 5	260	4 7				

The effects on blood-cholesterol and uric-acid levels are summarised in the accompanying table

All these patients were treated while up and about, no change was made in their usual diet or in their daily routine After treatment with aspirin a striking fall in blood-cholesterol level, and a smaller fall in uric-acid level, was observed in all cases In several cases, blood-cholesterol levels rose after the cessation of treatment and reverted to their original value

I conclude that aspirin has an effect, so far unexplained, on the metabolism of cholesterol

A SUCKER FOR EMPTYING THE INTESTINE

IN cases of small-bowel obstruction it is now the usual practice to empty the intestine at operation by means of a sucker The entire length can be cleared of fluid and gas by coaxing the instrument through successive loops of distended bowel

Because the available sucker ends are often too short to reach the whole length of small intestine, a special long sucker has been devised [1] for this purpose An alternative device, developed independently about the same time, has been made for me by Down Bros , Ltd , 21, St. Thomas' Street, London, S E 1

This sucker consists of a brass tube 6 in. long, with threads cut at each end so that it can be used to extend the standard Poole's sucker end by simply unscrewing the outer sheath and screwing in the extension tube, there is no need to extend the inner tube A $^1/_2$ in flange at the proximal end of the extension tube makes it easier to use

New Inventions

A SUCKER FOR EMPTYING THE INTESTINE

IN cases of small-bowel obstruction it is now the usual practice to empty the intestine at operation by means of a sucker The entire length can be cleared of fluid and gas by coaxing the instrument through successive loops of distended bowel

Because the available sucker ends are often too short to reach the whole length of small intestine, a special long sucker has been devised [1] for this purpose An alternative device, developed independently about the same time, has been made for me by Down Bros , Ltd , 21, St Thomas' Street, London, S E 1

This sucker consists of a brass tube 6 in long, with threads cut at each end so that it can be used to extend the standard Poole's sucker end by simply unscrewing the outer sheath and screwing in the extension tube, there is no need to extend the inner tube A $^1/_4$ in flange at the proximal end of the extension tube makes it easier to use

patient although serum-iron levels fell from 6260 µg per 100 ml to 1000 µg within seven hours If the drug increased diffusion of iron from the blood, it might be valuable in the first and most critical phase of iron intoxication in which shock with hæmoconcentration develops rapidly In rabbits poisoned with intravenous iron, shock developed within a few seconds (Brown and Gray 1955), it also appeared when animals were poisoned by intraduodenal instillation of iron in solution, a method which does not produce mucosal necrosis This evidence suggested that circulatory changes were a direct effect of excess iron in the vascular system If this were so, rapid removal of the excess might aid recovery from shock The rate of fall of serum-iron in our case did not appear to be faster than that recorded by Spencer (1951), whose case received no chelating agent Serum-iron levels in dogs poisoned with intraduodenal ferrous sulphate where higher in untreated animals than in those receiving edathamil intravenously immediately after iron was given (Bronson and Sisson 1960) Death was not prevented, however, and the amount of serum-iron did not appear to be the determining factor The only survivor was also given disodium orthophosphate into the stomach when iron was administered into the duodenum

The course of the child's illness followed closely the biphasic pattern emphasised by Prain (1949) and Spencer (1951) An initial period of shock, recovery from which could be attributed to the measures taken to increase plasma-volume and to correct acidosis, was followed about sixty hours later by a second period of coma The clinical diagnosis of hepatic coma was supported by very high levels of serum-transaminase, increased plasma-bilirubin values, changes in plasma-protein levels, and normal plasma-non-protein-nitrogen values The abnormal E E G records were also consistent with this diagnosis The second critical phase was successfully negotiated within forty-eight hours and recovery was then rapid The same sequence of events has been reported in severe cases which were not treated with chelating agents

Summary

A non-fatal case of acute iron poisoning in a boy, aged 2, is reported Treatment included the use of intravenous edathamil calcium-disodium (calcium disodium versenate), and its effect is discussed The plasma-iron content at the start of treatment was 44,000 µg In the following fifty-two hours 5416 µg of iron was found in the urine

The biphasic nature of the clinical course is again emphasised Relapse in our patient was the result of liver dysfunction

We are grateful to the consultant physicians of the department of child health and the department of pathology, United Bristol Hospitals, for their advice and their permission to publish this case

CANCER OF THE ŒSOPHAGUS

PALLIATION BY INTUBATION

W P Greening
F R C S
ASSISTANT CONSULTANT SURGEON

G S Ramsay
M B Lond, F R C S
RESEARCH ASSISTANT

THE ROYAL MARSDEN HOSPITAL, FULHAM ROAD, LONDON, S W 3

The most important function of any palliative procedure in cases of inoperable cancer of the œsophagus or of the cardia is the relief of dysphagia Obstruction in the œsophagus or the upper end of the stomach cannot always be relieved by radiotherapy, Souttar's tubes have certain disadvantages, and gastrostomy is a most undesirable procedure

Recently there has been a revival of interest in methods of inserting a tube through the obstruction, either via an œsophagoscope (Weisel et al 1959, Sachs 1959) or through a gastrostomy opening (Gourevitch 1959, Moghissi 1960)

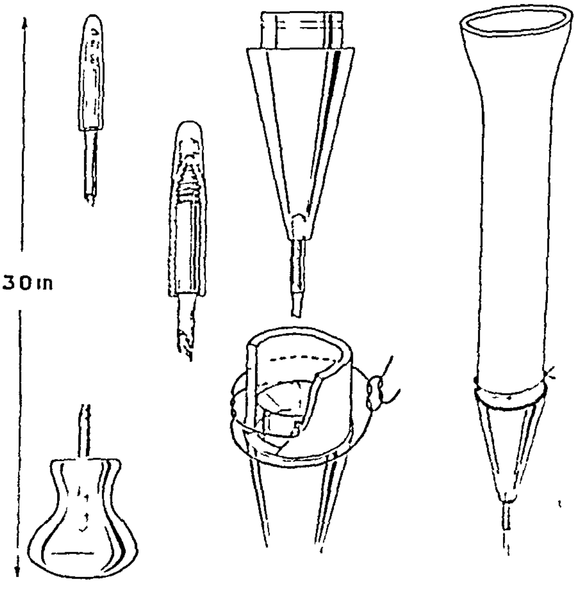
Ideally, after intubation, the patient should be able to swallow without difficulty, and there should be no restriction in the diet Gourevitch (1959) has summed up the main disadvantages of intubation through an œsophagoscope We would add another to his list—namely, the size of the tube that can be passed is limited by the diameter of the lumen of the œsophagoscope This is important because we believe that it is essential to insert as large a tube as possible, and this can only be done easily from below The danger of splitting the œsophagus, or of hæmorrhage from the growth, has been exaggerated, it is possible to dilate a malignant stricture much more widely than is generally believed

These points are important

1 The method should be simple Œsophagoscopy—particularly in the elderly patient—is not always either easy or safe

2 The tube should be of large diameter

3 The tube should be made of inert material, capable of being fashioned individually for each case, and available in different degrees of hardness to suit varying conditions



The œsophageal tube introducer

Over the past two years we have developed a method, used in 9 cases, which satisfies these requirements Polyvinyl chloride tubes, supplied in two degrees of hardness by Portland Plastics Limited, are used An introducer with interchangeable ends, to fit three different sizes of tube (numbers 30, 40, and 50), has been designed. A flange is made at the upper end of the tube This can be done quite simply by immersing the end of the tube in boiling glycerin, at the temperature of which (290°C) it becomes easily malleable It is then passed over a conical object of suitable size, and, on cooling, the splayed-out end remains a permanent flange The introducer (see figure) consists of 30 in of Bowden cable with a screw-threaded end, to which can be attached either a small 'Perspex' tip, or one of three perspex cones The cable is coated with "cold-cure" 'Silastomer' (Midland Plastics Limited), this is a silicone rubber covering which is flexible and can be used at temperatures up to 200°C

Technique

The inoperability of the tumour is determined either clinically or at operation A high anterior gastrotomy is then made and the introducer, with the perspex tip attached, is passed up the œsophagus and delivered through the mouth by the anæsthetist The tip is then unscrewed and the appropriate cone attached These cones are so designed that the base fits into the lumen of the tube, while the rim of the cone, which is of slightly larger diameter than the outside diameter of the tube, does not project, and thus the tube cannot catch in the growth as it is pulled through The tube is tied to the base of the cone by a thread, passed through the wall of the tube and through the channel provided in the base of the cone Traction on the introducer then causes the tube to pass easily down the œsophagus, until the flange is just above the growth The cone is then detached, and any excess of tube cut off, so that the lower end lies in the upper third of the stomach The gastrotomy is closed

We wish to thank the department of medical physics at the Royal Marsden Hospital for making the instrument, and Midland Silicones Limited for the supply of "cold-cure" 'Silastomer'

Preliminary Communication

BLOOD-CHOLESTEROL AND ASPIRIN

ARTERIOSCLEROSIS and cardiac infarction are particularly important problems at the present time Many workers consider that there is a definite relationship between the blood-cholesterol level and arteriosclerosis Various diets have been tried in arteriosclerotic diseases, and attempts made to lower the blood-cholesterol level by administering linoleic acid Dreyfuss[1] observed a rise in the blood-uric-acid level in some cases of arteriosclerosis, but emphasised that the blood-cholesterol level was not invariably raised I have noted that in some cases of arteriosclerosis not only the blood-cholesterol but also the blood-uric-acid level is raised

On the assumption that there might be a metabolic relationship betweeen cholesterolæmia and raised blood-uric-acid levels, an attempt was made to lower the blood-cholesterol level by decreasing the blood-uric-acid For this purpose small quantities of aspirin (1 5 g daily) were administered to 10 patients (6 men and 4 women) whose ages ranged from 38 to 65 years 6 of them had had myocardial infarction and 1 of these was also hypertensive, 2 were hypertensive, 1 had recurrent anginal pain, and 1 had peripheral arteriosclerosis

BLOOD-CHOLESTEROL AND BLOOD-URIC-ACID (MG PER 100 ML) BEFORE, DURING, AND AFTER TREATMENT WITH ASPIRIN 1 5 G DAILY

Case no	Before treatment		After 2 weeks treatment		After 1 month's treatment		After end of treatment	
	Cholesterol	Uric acid	Cholesterol	Uric acid	Cholesterol	Uric acid	Cholesterol	Uric acid
1	270	4 7	240	4 7	180	4 0		
2	370	6 2	220	6 2			370	
3	310	4 2	175	3 2	228	3 2		
4	330	5 2	286	5 0	230	6 0	310	6 2
5	270	4 0	230	5 0			300	4 2
6	350	4 8	280	4 0				
7	331	4 3	190	3 7				
8	240	5 0	198	4 35	215	5 4		
9	300	4 0	135	3 25				
10	342	4 5	260	4 7				

The effects on blood-cholesterol and uric-acid levels are summarised in the accompanying table

All these patients were treated while up and about, no change was made in their usual diet or in their daily routine After treatment with aspirin a striking fall in blood-cholesterol level, and a smaller fall in uric-acid level, was observed in all cases In several cases, blood-cholesterol levels rose after the cessation of treatment and reverted to their original value

I conclude that aspirin has an effect, so far unexplained, on the metabolism of cholesterol

Reviews of Books

Measurement of Subjective Responses

Quantitative Effect of Drugs HENRY K BEECHER, M D, Henry Isaiah Dorr professor of research in anæsthesia, Harvard University London and New York Oxford University Press 1960 Pp 494 102*s*

THE main problems of therapy are to relieve, and if possible abolish, pain and to ease anxiety, and there are age-old remedies for these conditions and brand-new ones hot from the chemist's bench The difficulty is to find the agents which work best and have the fewest disabling and harmful side-effects This is not easy since we have little knowledge of the physiological basis of anxiety, though we all think we mean the same thing when we use the word Again, we cannot describe pain nor compare one person's pain with that of another A good controlled experiment demands the use of dummy drugs, and this raises a question of ethics Should sufferers be given placebos? Dr Beecher points to the interesting fact that the worse a patient feels the more probable is it that a placebo will help him, which seems to show that pain and anxiety render patients more suggestible Placebos may even induce undesirable side-effects As far as relief of pain is concerned it is possible that few drugs relieve the pain itself, but many lessen the reaction to pain, and it is the reaction which is distressing, as the response of people who have undergone frontal leucotomy or lobotomy illustrates Pain, like all perceptions, is not pure, but contaminated by the reaction component, and it is this rather than the pain per se which differs so much from person to person, or in the same person in different conditions

This last point raises the question of the usefulness of experimental as against clinical assays of pain-relieving drugs In experimental conditions the human subject suffers little anxiety, he knows that the trauma is transitory and unimportant He is, therefore, a bad experimental animal On the other hand, the use of animals yields results which are clinically useful since to the animal the experimental threat is as great as any other and holds the same elements of anxiety Thus, the animal and the sick man hold remarkably similar views on the efficacy of certain drugs These are some of the facts discussed by Dr Beecher He has planned a number of ways in which errors of assay can be avoided and imponderables measured to some extent He deals with pain- and anxiety-relieving substances, and a number of others affecting nausea, pruritus, cough, euphoria, sedation, and so on He makes the interesting statement that many cough-suppressing drugs do not really reduce the frequency of cough but do reduce the patient's awareness of it Clearly this is an important and interesting book, well worth study, especially since the methods advocated can be used for measurement of reactions, quite apart from the effect of drugs on the causes of the reactions

The Neurological Examination of the Infant

ANDRE-THOMAS, YVES CHESNI, S SAINT-ANNE DARGASSIES Editors R C MAC KEITH P E POLANI, E CLAYTON-JONES London National Spastics Society 1960 Pp 50 5*s*

THIS concise, informative, and well-produced guide to the neurological examination of the infant is published as a hard-cover supplement to the *Cerebral Palsy Bulletin* Pædiatricians and others will be grateful for the information in this handy but durable volume because it is not readily accessible elsewhere although essential for the acquirement of the important skills required

The first part which deals with the neurological examination of the newborn, is based on a regional scheme which enables the examination to be carried out in a methodical well-organised way This is described with great clarity both in words and in diagrams The second part is concerned with the examination of older infants and has perforce to consider the evolution of each function separately This makes it less helpful as a technical handbook, and in spite of the inherent dangers it might have been useful to include a chronological table synthesising the approximate neurological
expected at appropriate months during the first yea

Hospitals Group, Rhodesia, M GELFAND, C B E, M D, F R C
consultant physician, European and African Hospitals, Salisbu
Rhodesia Edinburgh E & S Livingstone 1960 Pp
7*s* 6*d*

FROM a study of 300 European and 100 African cases,
authors of this valuable book define a number of import
differences from the more widely known Egyptian form of
disease and draw attention to its varied manifestations in wh
and coloured races The disease is so endemic among Afric
that the early symptoms are often disregarded and advice
sought only in the later stages On the other hand, the a
incidence among Europeans at the time of diagnosis is consid
ably lower This difference may in part account for the f
that no cases of carcinoma in association with bilharziasis w
encountered among Europeans although in Africans they w
not uncommon Neither race, however, seems particula
prone to secondary urinary calculi The cystoscopic appe
ances and radiological findings in various phases of the dise
are discussed in detail and amplified by a number of w
chosen illustrations

In the matter of treatment the authors emphasise the valu
pyelography in conjunction with instrumental examinatio
distinguishing between the effects of ureteric obstructio
reflux and in determining the appropri
complications in the upper urinary tract

New Ideas on Epidemic Virus Infections

MANY of the important epidemic virus diseases of man are transmitted directly from person to person without the intervention of an intermediate or alternate host. Of the factors which influence susceptibility, such as inherent or acquired immunity, some are quite well understood, but the factors affecting virus transmission are much less well defined. Even in such a well-studied disease as poliomyelitis it is uncertain whether virus from the throat or from the fæces is the more important. In many respiratory infections infected secretions are probably the source of the virus, but we do not really know exactly how and where the virus reaches its next host. We would expect to find that such virus infections are more readily transmitted when people live under crowded conditions, and when standards of hygiene are low, and this seems to be true for poliomyelitis and the common acute respiratory virus infections. It is well known, however, that some virus diseases tend to become epidemic in the summer and others in the winter.

ANDREWES[1] has pointed out that, although Asian influenza was seeded widely in many countries by modern means of travel, yet in most places epidemics developed only when the cold season came on. Temperature could not determine the "winter factor", for otherwise "the tropics would never get epidemics at all", and he suggested that in winter the main change was that people were more crowded where they lived and worked—a change which applies particularly to children who go back to school in the autumn, and who often get colds then. HOPE-SIMPSON[2] found an astonishingly close correspondence between increase of outdoor temperature and decrease in the number of patients who consulted him on account of colds. In another study he showed over a three-year period in a group of volunteers that there was a similar correlation between the appearance of symptoms of colds and decrease of temperature 1 ft. below the surface of the earth. He suggested that the reason for these correlations is that in cold weather we heat our rooms and thus reduce the relative humidity of the air, and he found that switching on a one-bar electric fire in an average-size room with the window and door open reduced the relative humidity from over 80% to about 50% as the temperature rose from 20° to 30°C. This drier air, by drying the mucous membranes of the respiratory tract, may increase susceptibility to infection. WADDY[3] earlier proposed that low absolute humidity could act in this way to aid the spread of airborne disease, and one of the illustrations he used to support his view was the influenza pandemic of 1918–19. Nevertheless, when volunteers are inoculated with cold viruses at a wide range of humidities and temperatures the frequency with which colds develop does not seem to vary.[4 5]

Polioviruses, by contrast, are more prevalent in the later summer months, and the explanations of this have run on the same lines as those of changes in the prevalence of other infectious agents found in the fæces—i.e., greater frequency of fæcal-feeding flies, and the larger consumption of uncooked food. These factors must be assumed to overcome the effect of larger amounts of light and higher temperatures, which would tend to reduce the amount of surviving virus. Humidity is not generally regarded as an important influence on the transmission of polioviruses.

Laboratory experiments by HEMMES et al.[6] in Utrecht may cause us to revise our thinking, and may reconcile some apparent conflicts. These workers prepared from virus suspensions aerosols which they held in a closed system, measuring the rate at which virus infectivity was lost. Temperature and absolute humidity had little effect on this rate, but it was strongly influenced by relative humidity, and there seemed to be a sharp distinction between results obtained at a relative humidity of 40% or lower and one of 50% or higher. In the case of influenza virus (PR8 strain) inactivation of infectivity was slow in the drier conditions and over 10 times more rapid in the moister conditions. The reverse held for a strain of poliovirus type 1, which survived well at relative humidities above 50%, but which at 40% or lower was inactivated so quickly that no virus could be recovered from an aerosol 30 seconds after spraying. Experiments of this sort have many technical snags: some of the aerosol may be lost on the wall of the container, and the composition of the suspending medium or the medium in which samples were collected may greatly affect the survival of viruses. But it is very unlikely that such technical difficulties would alter the relatively greater rate of inactivation of influenza virus in humid air and of poliomyelitis in drier air. In fact the observations with influenza have been confirmed independently[7] in experiments conducted by a somewhat different technique. HEMMES et al. point to the correlation between low indoor relative humidity and increased prevalence of influenza, and between high indoor humidity and increased prevalence of poliomyelitis. Their calculations suggest that in the colder months the relative humidity indoors drops below the critical zone of 40–50% which was found in their experiments. Their hypothesis, then, is that seasonal variations in the prevalence of these two virus infections result from variations in the relative humidity indoors, which in turn affect the chances of survival of the viruses in the dried state

[7] Harper G L Unpublished.

This hypothesis has the great virtue that it can be readily tested Many different viruses are now known to cause respiratory disease in winter, while many other members of the enterovirus group tend, like polioviruses, to be found in summer It should not be difficult to compare the survival of some of these viruses at high and low relative humidities with the known facts of their epidemiology, and thus to substantiate or refute this interesting suggestion

Endocrine Exophthalmos

THE exophthalmos associated with Graves' disease is commonly of minor importance compared with the thyrotoxicosis it is usually mild and rarely accompanied by paralysis of the external ocular muscles By contrast, in the exophthalmos associated with exophthalmic ophthalmoplegia,[1] thyrotoxicosis is usually mild or has been relieved by treatment or replaced by frank myxœdema, but the paralysis of external ocular muscles is often pronounced and may become complete and vision may be jeopardised by secondary infection or vascular thrombosis These two clinically different types have been termed thyrotoxic and thyrotrophic exophthalmos respectively, implying that the former results from increased secretion of thyroid hormone and the latter from increased secretion of thyroid-stimulating hormone (T S H) These terms are wholly misleading since every gradation between the two syndromes can be found, the pathological anatomy is essentially the same, and there is no evidence that increased secretion of either the thyroid hormone or T S H plays a major part There is, however, experimental evidence that exophthalmos is produced more easily in the hypothyroid animal[2]—an observation which may be relevant to the severity of eye signs in exophthalmic ophthalmoplegia and their mildness in Graves' disease

The principal agent responsible for experimental proptosis was found to be present in extracts of pituitary tissue,[3] [4] and in 1953 Dobyns and Steelman[5] separated the exophthalmos-producing substance (E P S) from T S H by differential solubility in trichloracetic acid They tested it by its capacity to produce exophthalmos in the minnow, *Fundulus heteroclitus* Clinical evidence in support of the experimental work has been accumulating In 1956 two groups[6] [7] described their work on the measurement of T S H in serum in a total of 35 patients with thyrotoxicosis or exophthalmic ophthalmoplegia They used different techniques, and their results at best were only semiquantitative Both groups were generally able to detect T S H in the serum of their patients one[6] found no correlation with the degree of exophthalmos, while the other[7] found some evidence suggesting that T S H might occasionally be increased with severe exophthalmos Adams and Purves[8] pointed out that T S H is normally present in high concentration in the serum of patients with myxœdema and that it is suppressed by treatment with thyroid hormone They suggested that the presence of normal amounts in the serum of thyrotoxic patients is surprising and may indicate a failure in the mechanism for its suppression—a failure that may be the cause of Graves' disease There is no good evidence, however, that T S H is the cause of exophthalmos

In 1954 Dobyns and Wilson,[9] using the minnow, demonstrated E P S in the serum of 6 patients with exophthalmos and suggested that the degree of response in the fish was correlated with the severity of the exophthalmos This work has been extended by McGill[10] using the goldfish, *Carassium auratus*, and by der Kinderen et al[11] using the carp, *Cyprinus carpio* Both groups developed reasonably satisfactory quantitative procedures and found evidence suggesting that the active principle causing exophthalmos was the same in serum and in pituitary extracts They both examined the serum from a large series of people and detected an abnormally high level in patients with progressing exophthalmos, a normal level in those with stationary or regressing exophthalmos or with myxœdema, and a low level in those with pituitary failure There is therefore clinical evidence to support the claim that exophthalmos is caused by increased secretion of E P S

Rundle and Pochin[12] and Dobyns[13] showed that protrusion of the eyeball is the result of an increase in the bulk of the retrobulbar tissues The amount of fat in the fat depots is much increased, and the extraocular muscles are greatly enlarged and their fat content may be doubled Dobyns claimed that in the laboratory animal the fat is unusually gelatinous and is infiltrated with leucocytes, lymphocytes, and tissue macrophages, and the amount of fat in the muscles is closely correlated with muscular weakness Similar but less severe changes may affect skeletal and cardiac muscle, and large amounts of fat are found in the liver, kidneys, and epithelium besides large phagocytic cells in the lungs, spleen, and lymphnodes Evidently the effect of E P S is widespread, and indeed it is highly improbable that the pituitary gland would produce a hormone which specifically caused exophthalmos It is more likely, as McGill suggests, to be a general metabolic hormone, possibly influencing water partition in fat deposits, and giving rise to ocular protrusion only when secreted in excess

The treatment of endocrine exophthalmos has been reviewed by Brain[14] No specific endocrine therapy has been proved to be uniformly effective Œstrogens and thyroid extract have been tried extensively, but

there is neither physiological nor clinical evidence to suggest that these will suppress the secretion of E P S Irradiation of the pituitary gland is the most logical treatment and appears to be effective in some cases, but in general the suppression of any pituitary secretion by irradiation tends to be slight and transient, as is shown by experience of this method in Cushing's syndrome. Irradiation of the orbits has its advocates, but it is difficult to establish that any improvement is not the result of accidental irradiation of the pituitary gland. Hypophysectomy or section of the pituitary stalk is apparently very effective, but is drastic[15], and, for the present, the most reliable treatment for severe cases is tarsorrhaphy or orbital decompression.

Bathing-water

IN this climate bathing is an unnatural habit and it may be for this reason that so many ills have been attributed to it. Warnings of the danger of immersion after meals, in convalescence, or when drenched with sweat are commonplaces of our folk medicine. The published evidence of infections after bathing is slight and not always convincing, but it is reasonable to distinguish between bathing in a modern swimming-bath and in natural waters fouled by unknown concentrations of human and animal excreta from all orifices The water in a swimming bath circulates continually through a filtration and chlorination plant. It can be polluted by no-one except the bathers and, though the degree of chlorination recommended by the Ministry of Health is not immediately bactericidal, the level of bacterial contamination is kept low
